Sources of Noise

Problem Definition

Outline

- Classical Denoising
 - Spatial Methods
 - Transform Methods
- State-of-the-art Methods
 - GSM – Gaussian Scale Mixture
 - NLM – Non-local means
 - BM3D – Block Matching 3D collaborative filtering

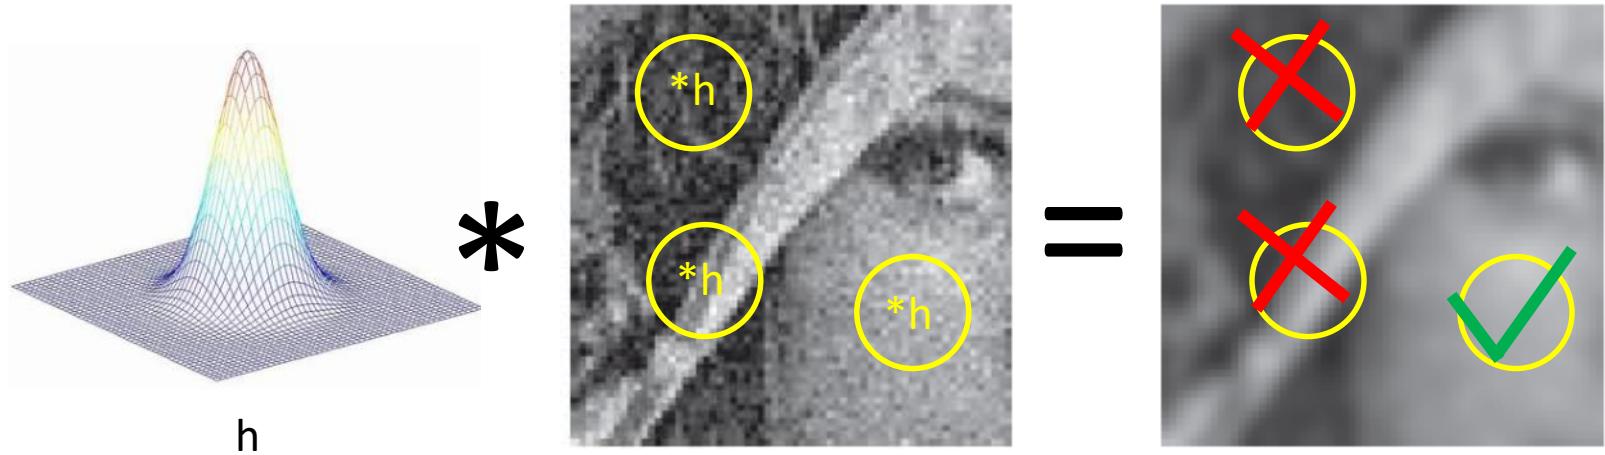

Denoising in the Spatial Domain

- The “classical” assumption:
Images are piecewise constant

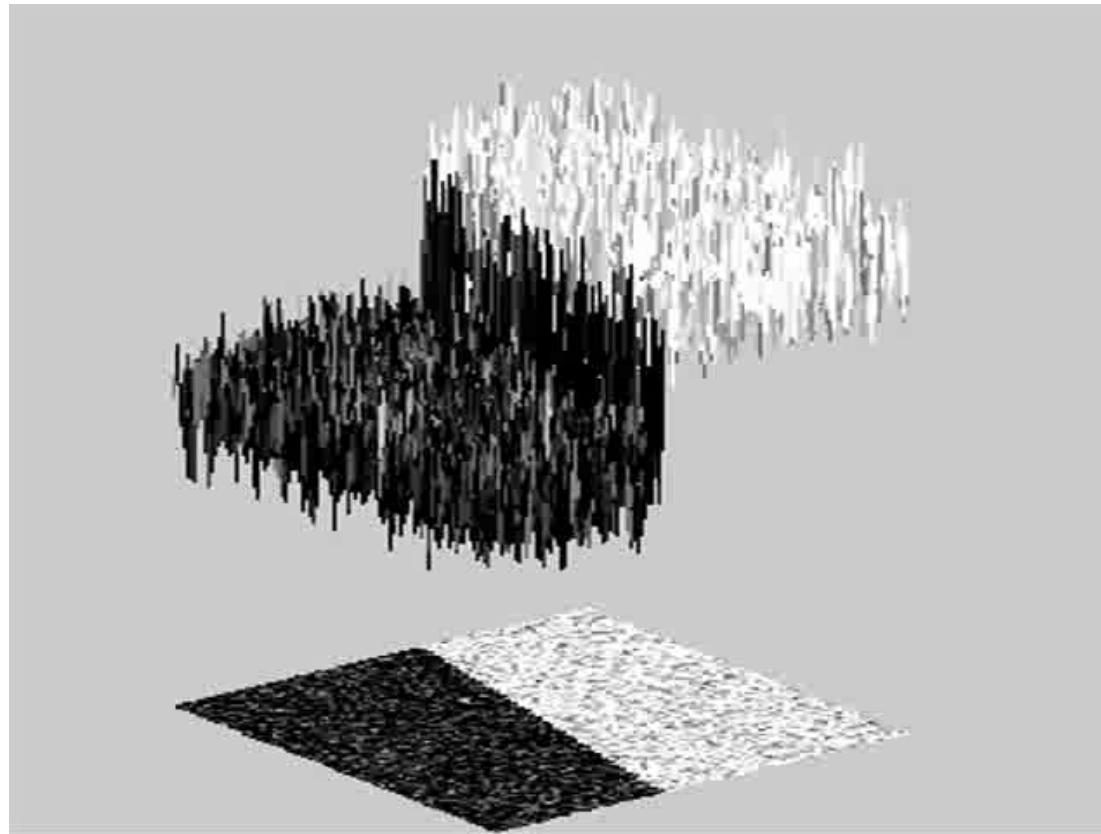

- Neighboring pixels are highly correlated
⇒ Denoise = “Average nearby pixels” (filtering)

Gaussian Smoothing

$$\hat{x}(i) = \frac{1}{C_i} \sum_j y(j) e^{-\frac{\|i-j\|^2}{2\sigma^2}}$$

Toy Example

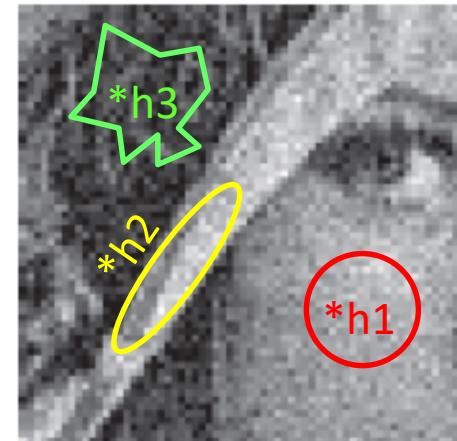

How can we preserve the fine details?

Local adaptive smoothing

- Non uniform smoothing

Depending on image content:

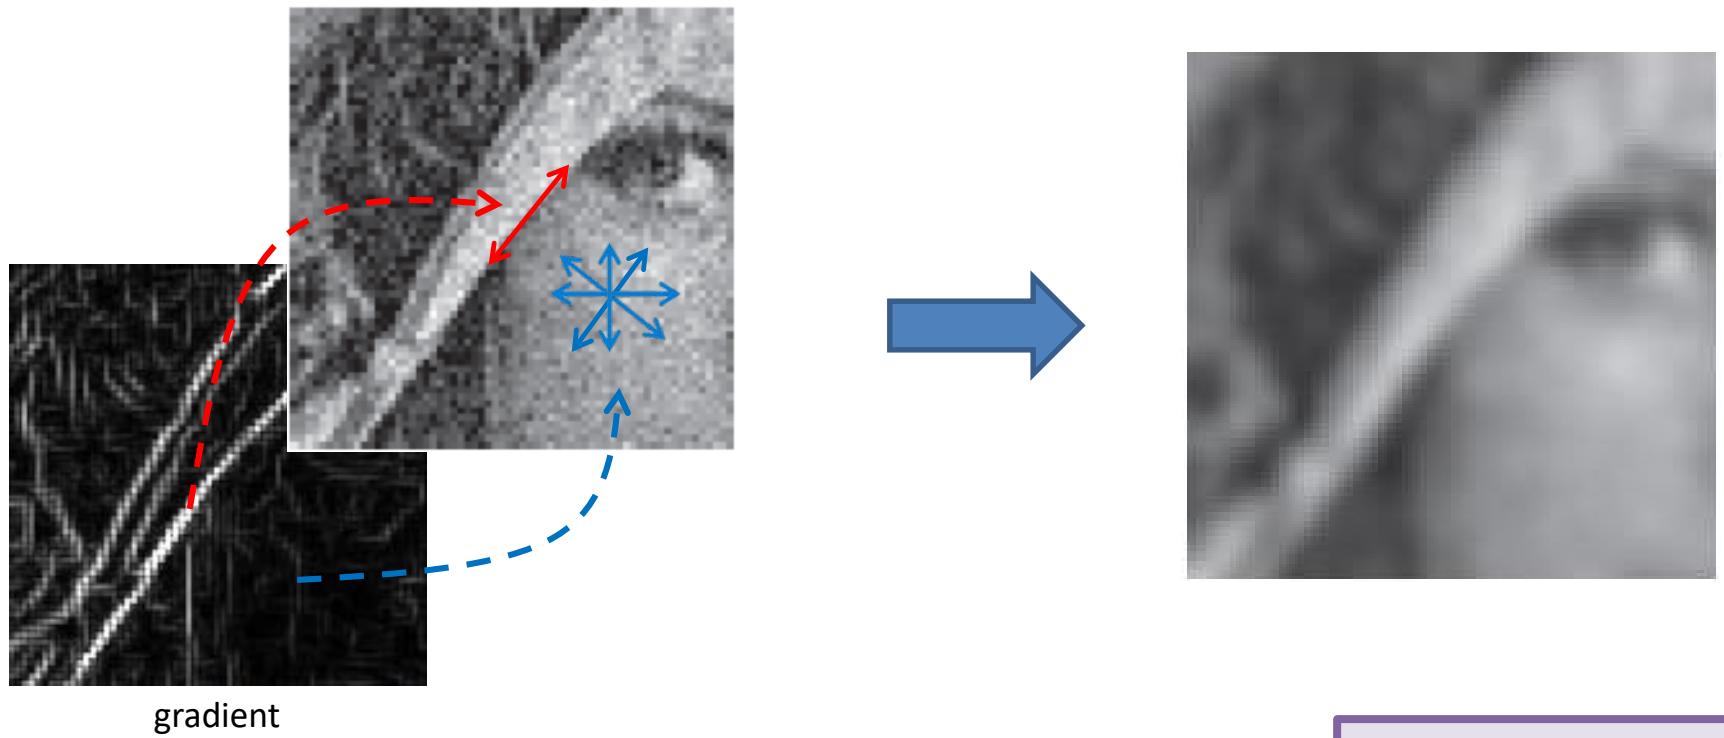

- Smooth where possible
- Preserve fine details

How?

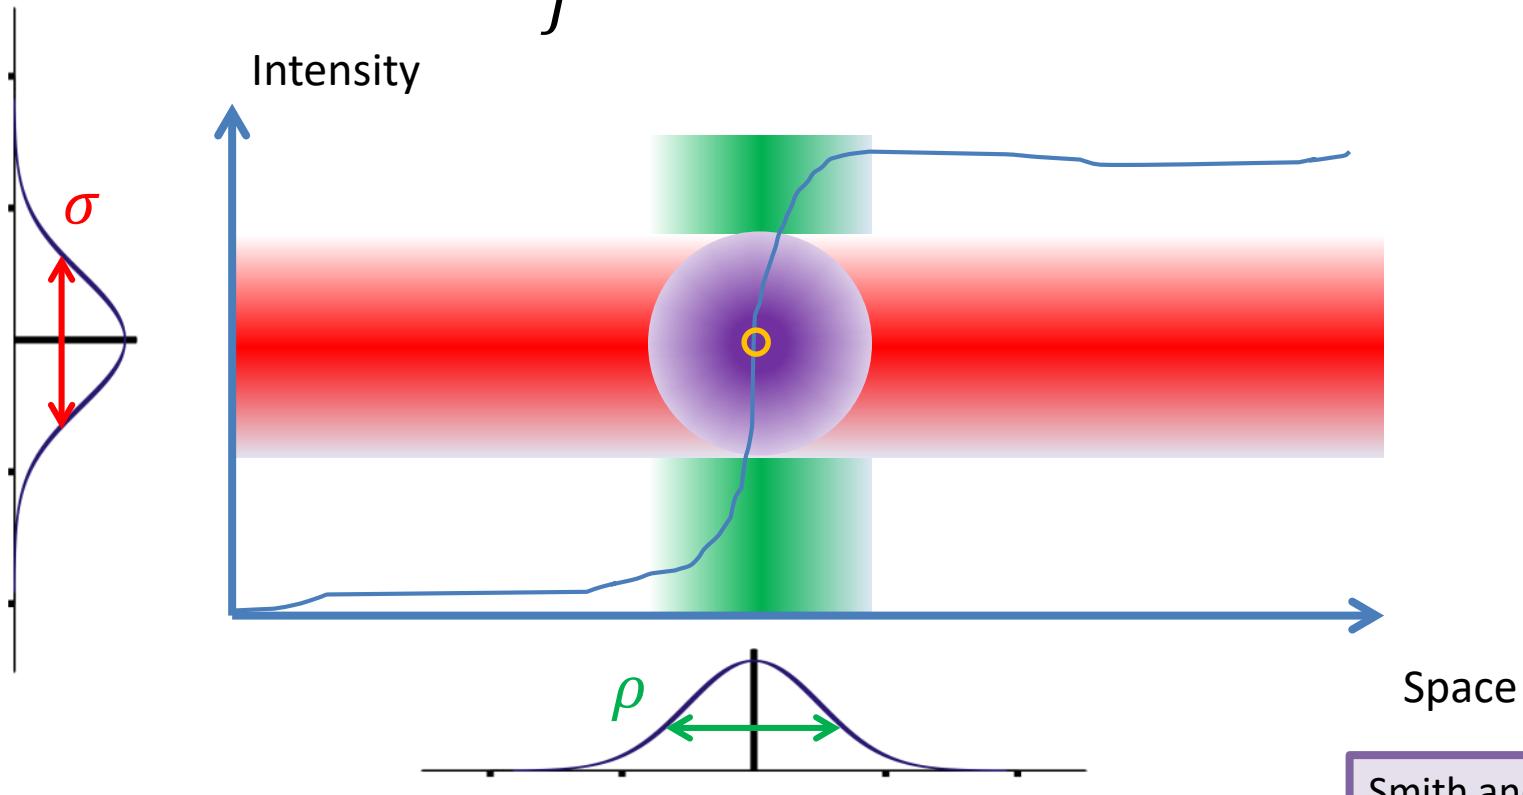

Anisotropic Filtering

- **Edges** \Rightarrow smooth only along edges
- “Smooth” regions \Rightarrow smooth isotropically

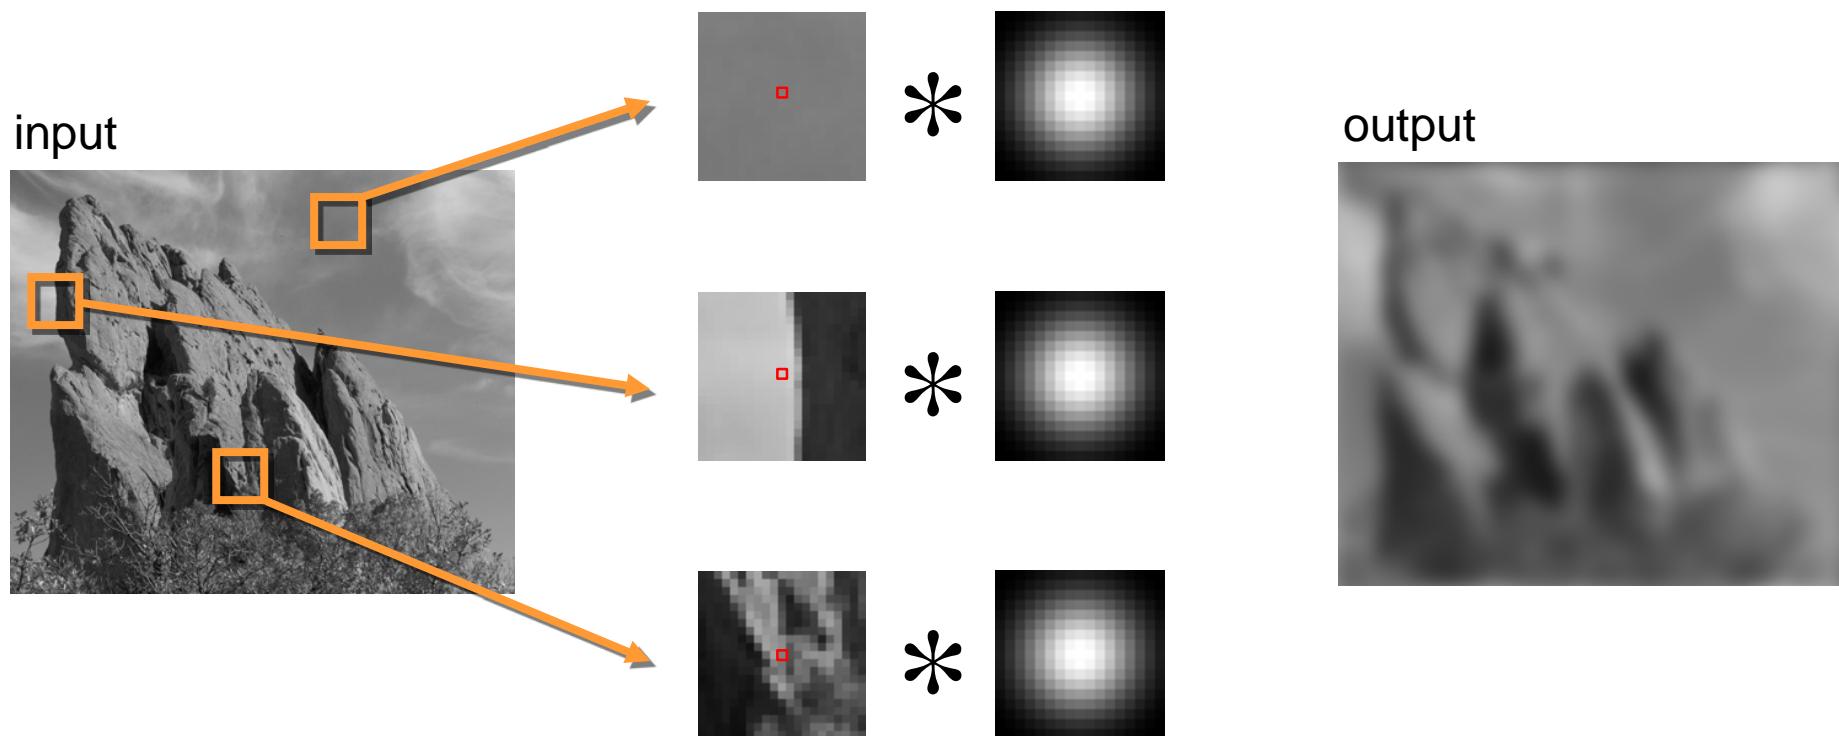

Bilateral Filtering

$$\hat{x}(i) = \frac{1}{C_i} \sum_j y(j) e^{-\frac{\|i-j\|^2}{2\rho^2}}$$

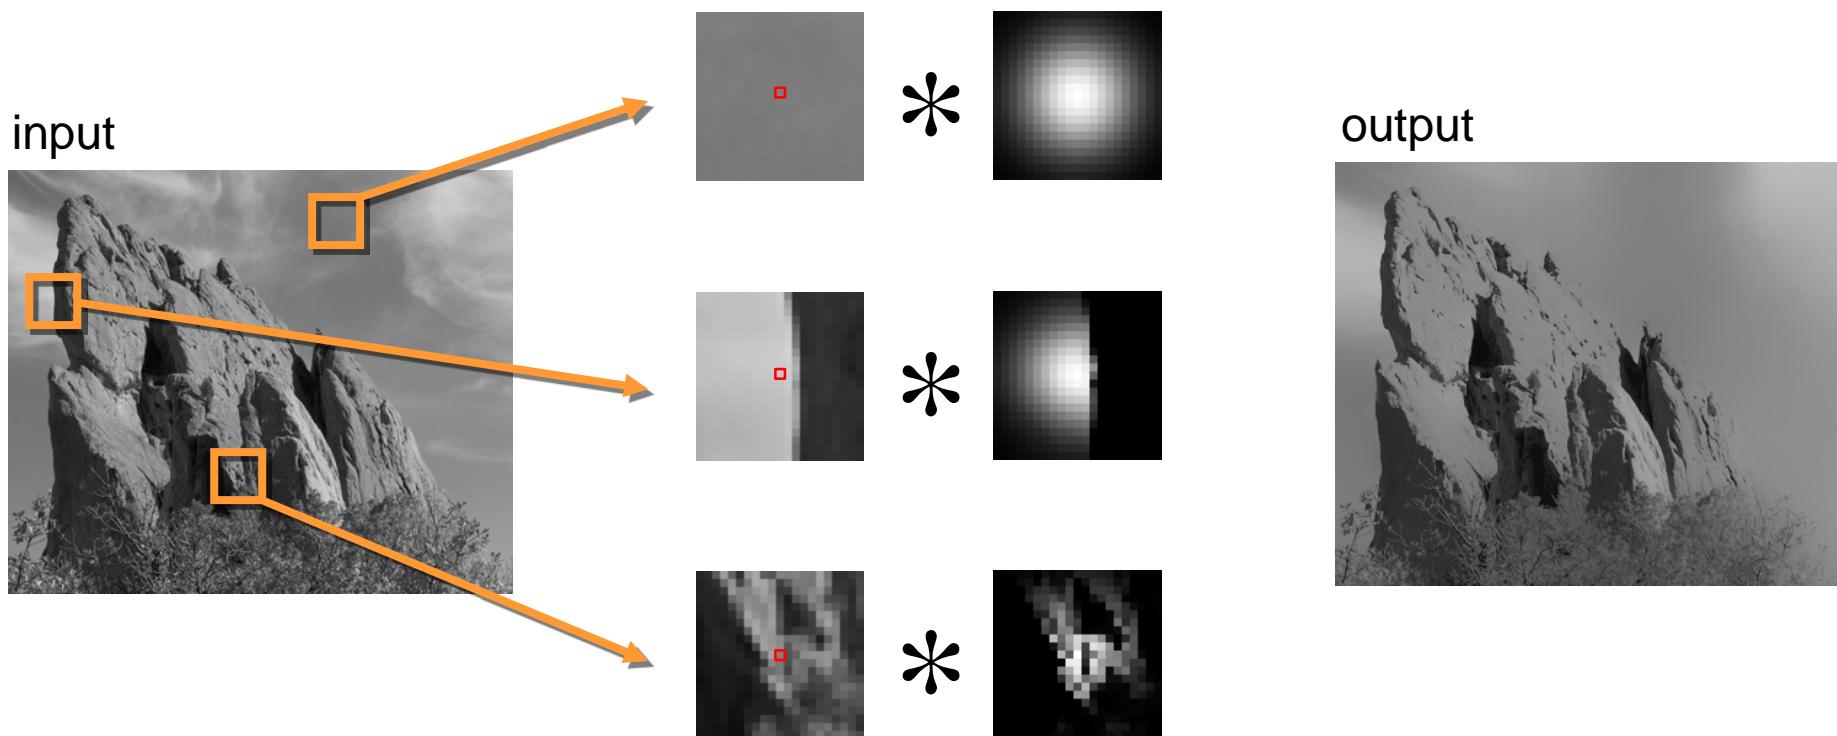

Gaussian Smoothing

Same Gaussian kernel everywhere
Averages across edges \Rightarrow blur

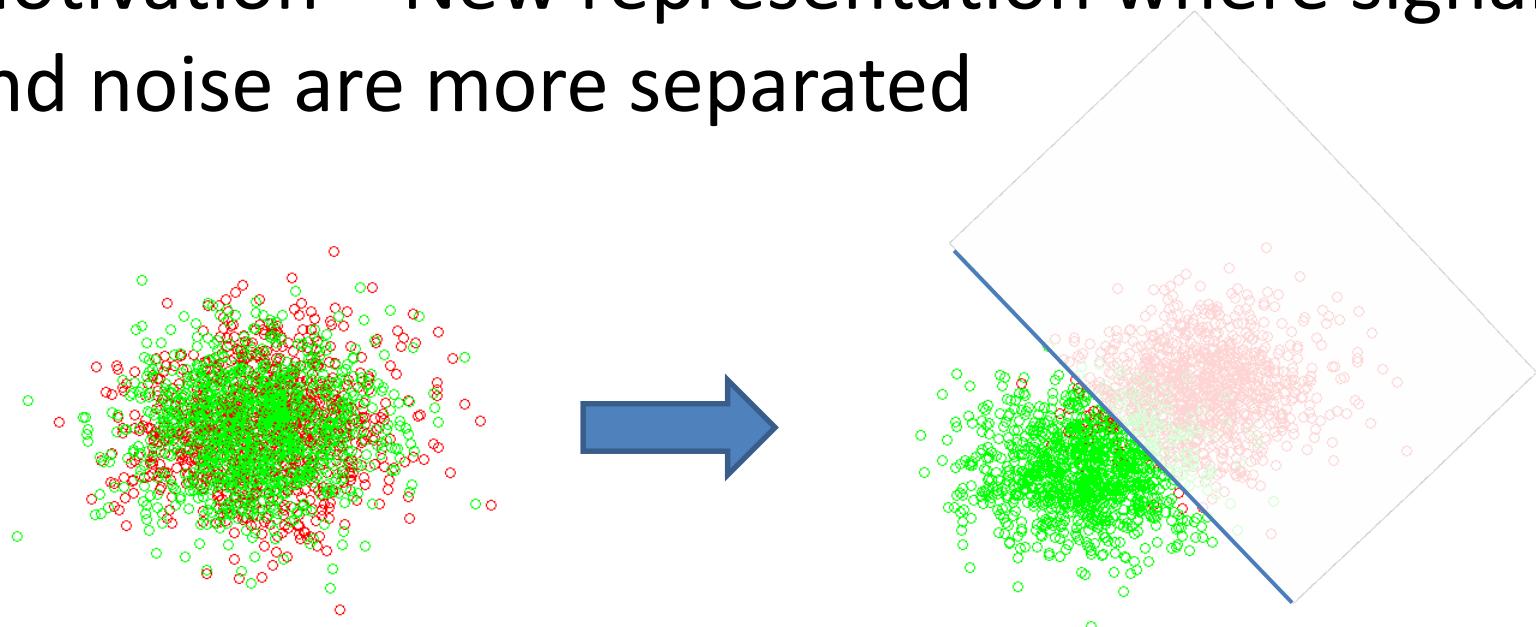

Bilateral Filtering

Kernel shape depends on image content
Avoids averaging across edges

Denoising in the Transform Domain

- Motivation – New representation where signal and noise are more separated

- Denoise = “Suppress noise coefficients while preserving the signal coefficients”

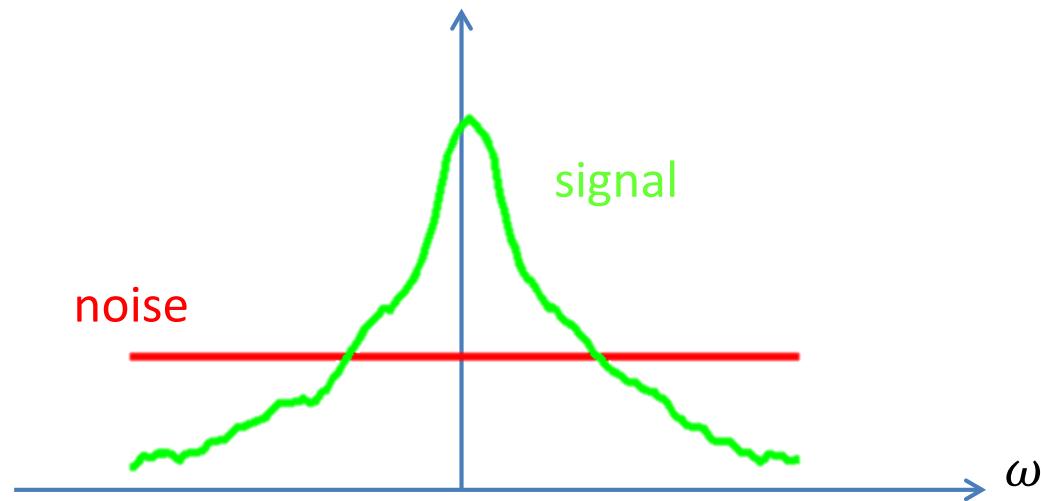

Fourier Domain

- Noise

White \Rightarrow spread uniformly in Fourier domain

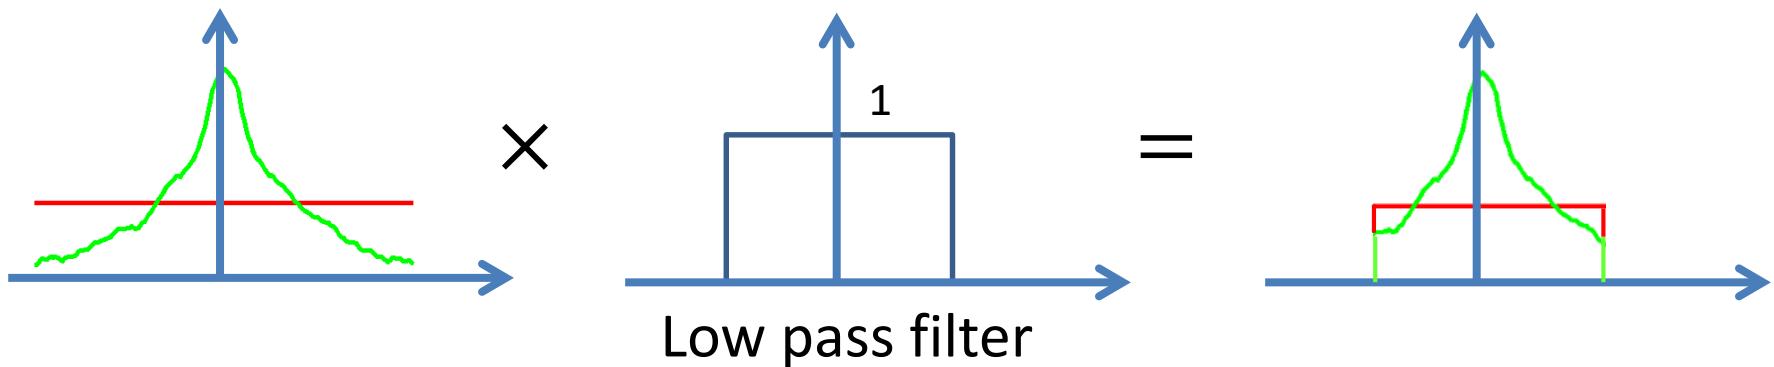

- Signal

Spread non-uniformly in the Fourier domain

Low-Pass Filtering

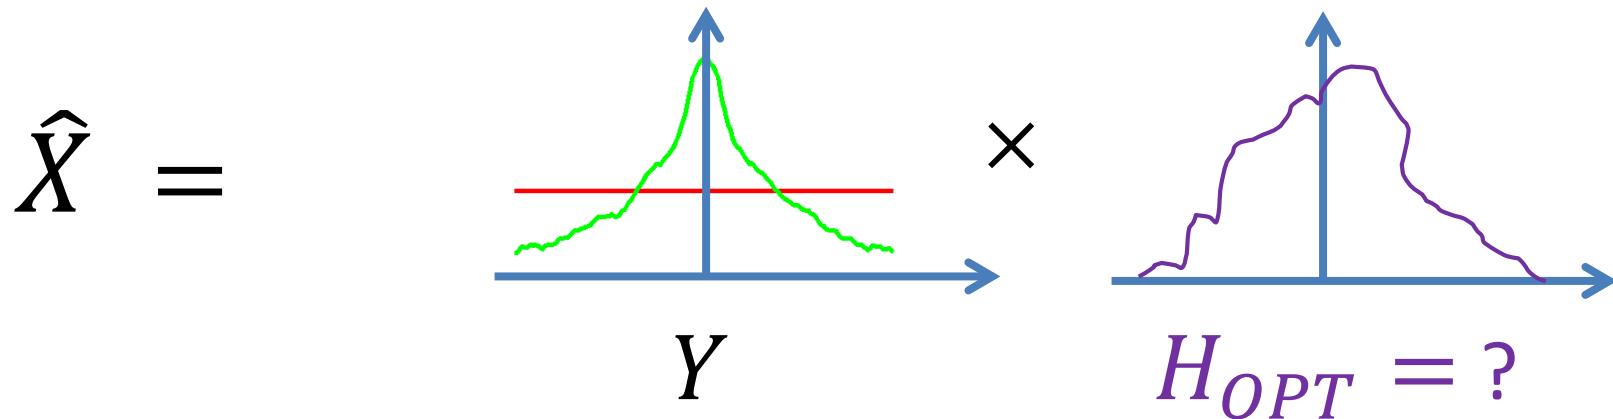

- Low pass with some cut-off frequency
- Keeps most of the signal energy

Equivalent to Global Smoothing

Looking for an Optimal Filter

$$\hat{X}(\omega) = Y(\omega)H(\omega)$$

Assumption: Signal and Noise are
Stationary independent random processes

The Fourier Wiener Filter

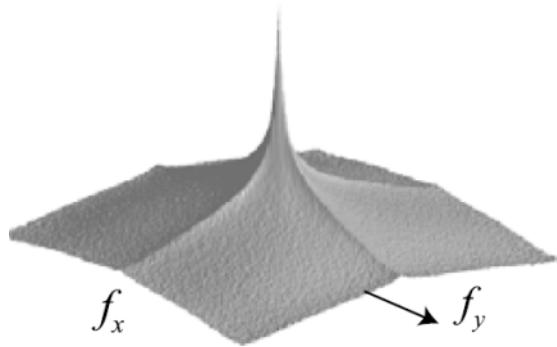

$$\hat{X}(\omega) = \underbrace{\frac{|X(\omega)|^2}{|X(\omega)|^2 + |N(\omega)|^2}}_{H_{OPT}(\omega)} Y(\omega)$$

- $|X(\omega)| \gg |N(\omega)| \Rightarrow H(\omega) \approx 1 = \text{Keep}$
- $|X(\omega)| \ll |N(\omega)| \Rightarrow H(\omega) \approx 0 = \text{Suppress}$
- Soft and adaptive thresholding

Optimal Linear Mean Square Error Estimator

Fourier Wiener Filter in Practice

- Use a model for $|X(\omega)|^2$ - for **example**:

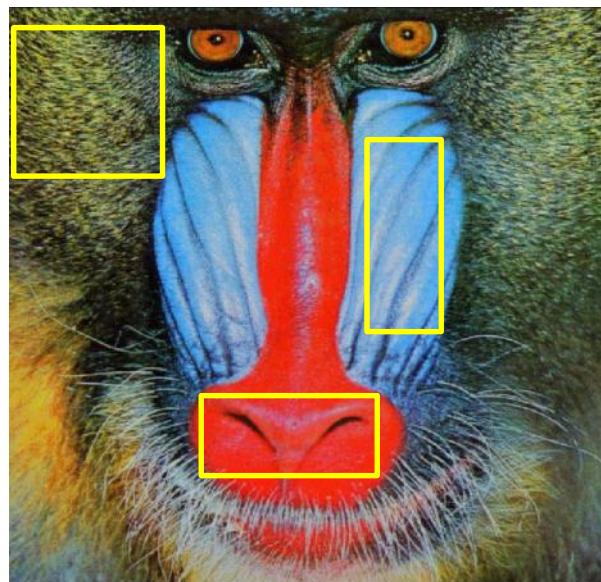

or $|X(\omega)|^2 = \frac{A}{(\alpha^2 + \|\omega\|^2)^{1+\eta}}$

- Use $|Y(\omega)|^2$ instead (empirical approach)

$$|X(\omega)|^2 = g[|Y(\omega)|^2]$$

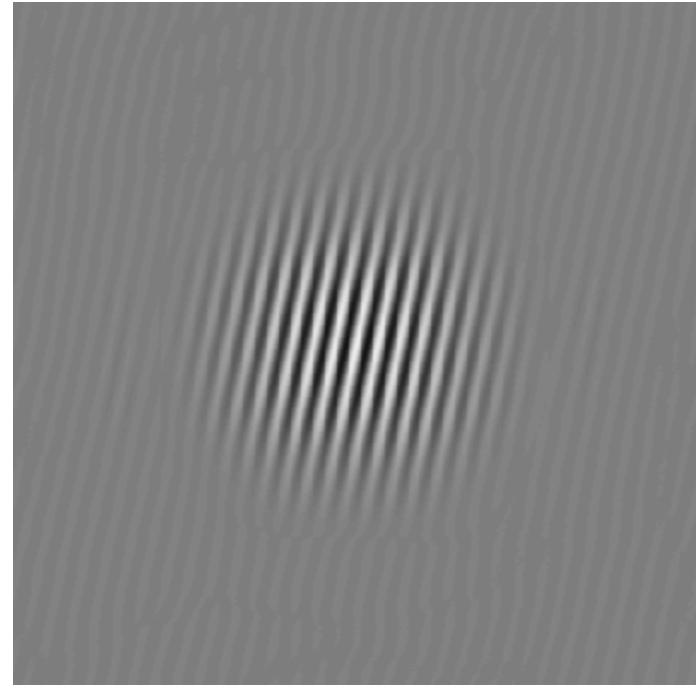

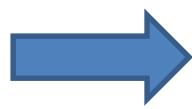

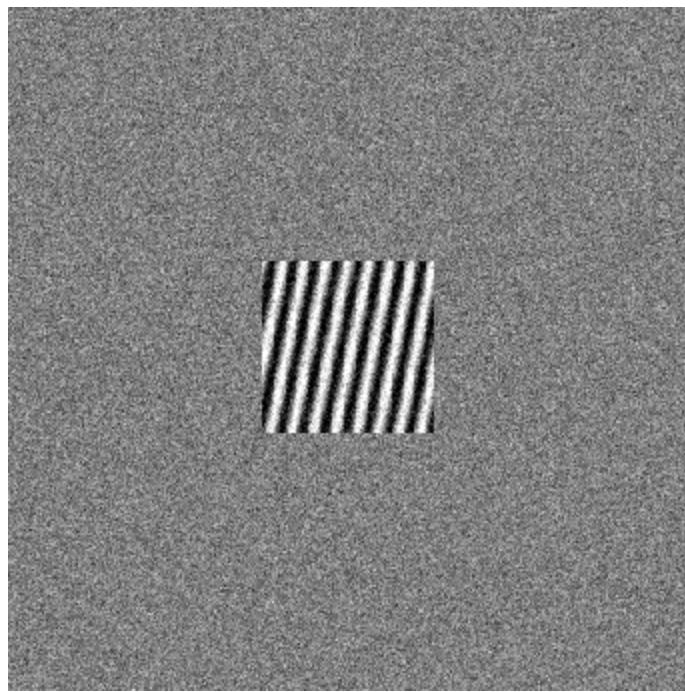

Why isn't it enough?

- We assumed stationarity:
“statistics of all image windows is the same”
- But natural images are not stationary

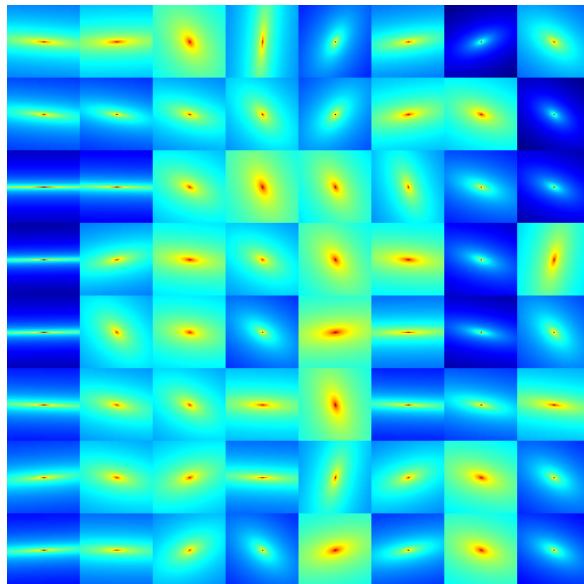

Why isn't it enough?

- Mismatches and errors \Rightarrow global artifacts

The Windowed Fourier Wiener Filter

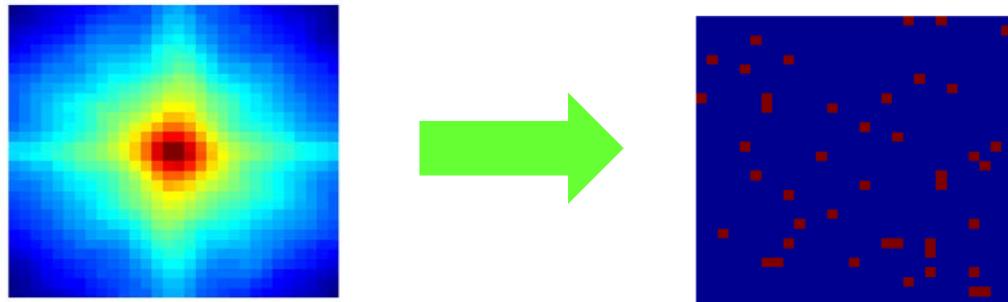

- Image has a local structure
⇒ Denoise each region based on its own statistics

Perform Wiener filtering in image windows

Can we do better?

- Why restrict ourselves to a Fourier basis?
- Other representations can be better:
 - Sparsity \Rightarrow Signal/Noise separation
 - Localization of image details

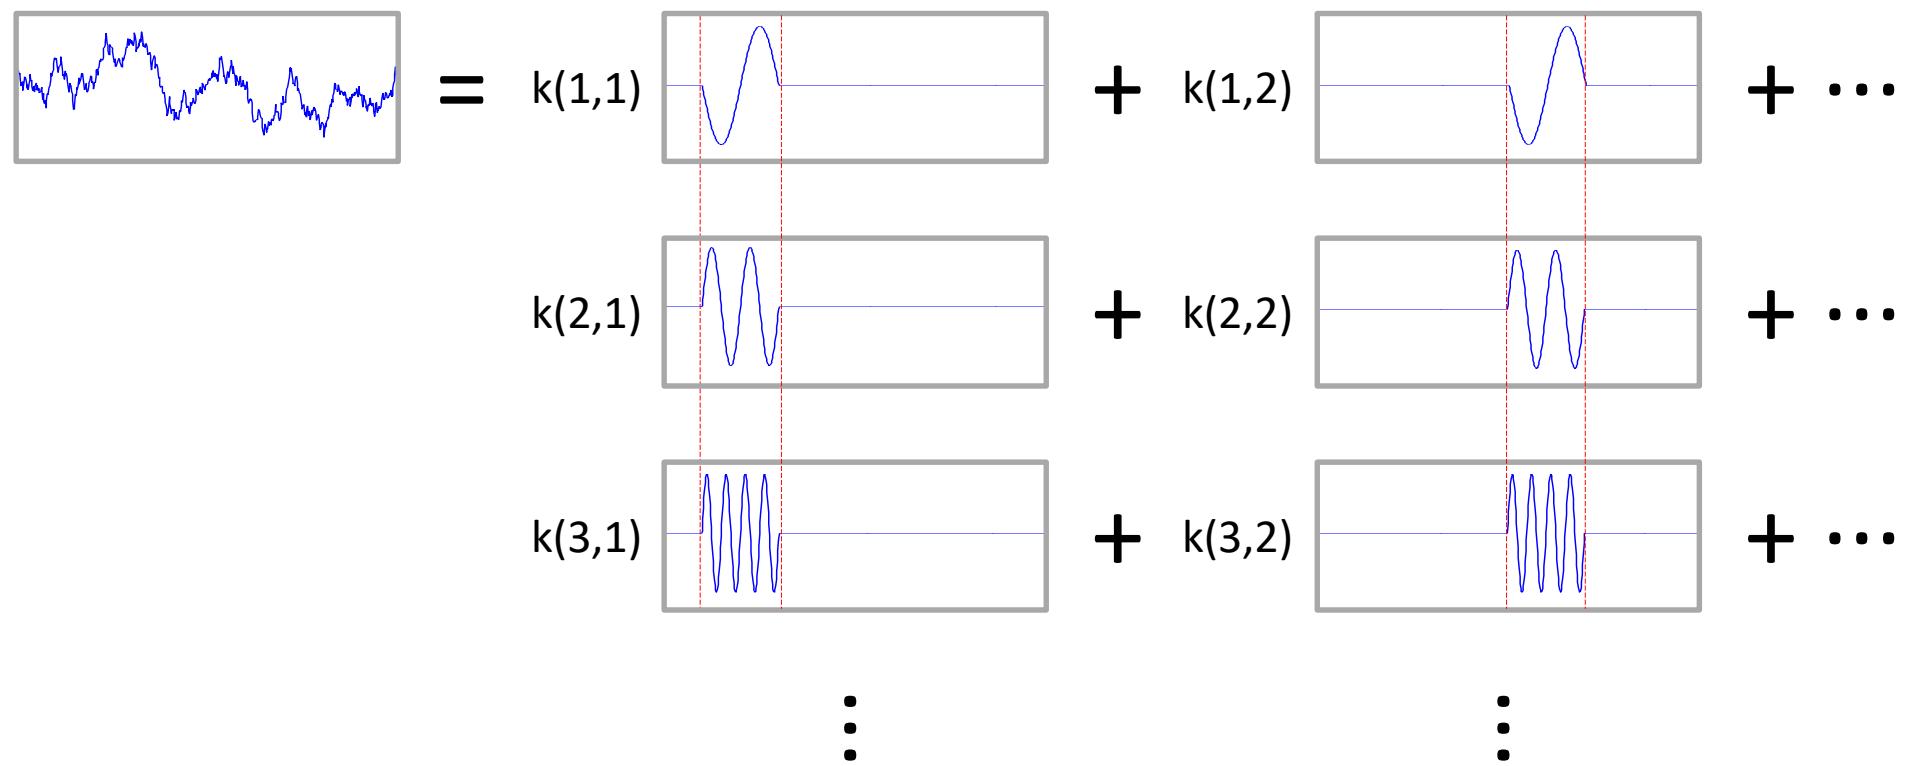

Wavelets

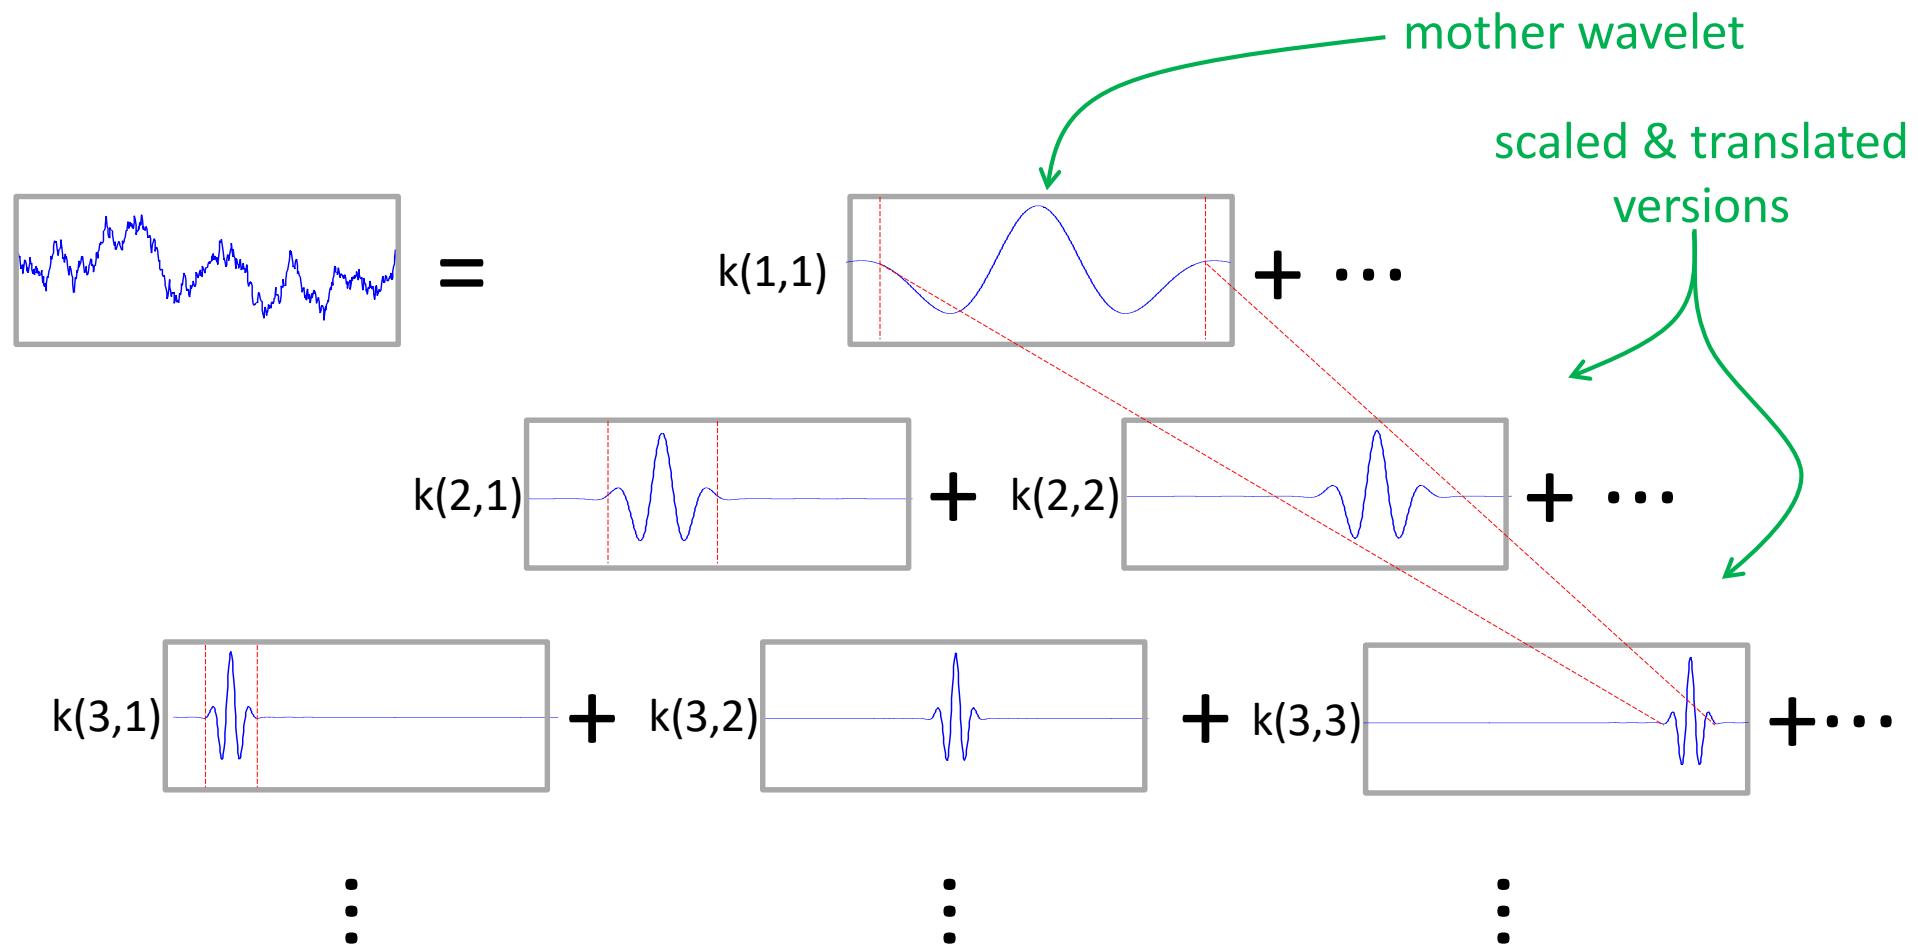

Fourier Decomposition

$$\begin{matrix} \text{[Noisy Signal]} \\ = k(1) \text{ [Low-Frequency Waveform]} + \\ k(2) \text{ [Medium-Frequency Waveform]} + \\ k(3) \text{ [High-Frequency Waveform]} + \\ \vdots \end{matrix}$$

Windowed Fourier Decomposition

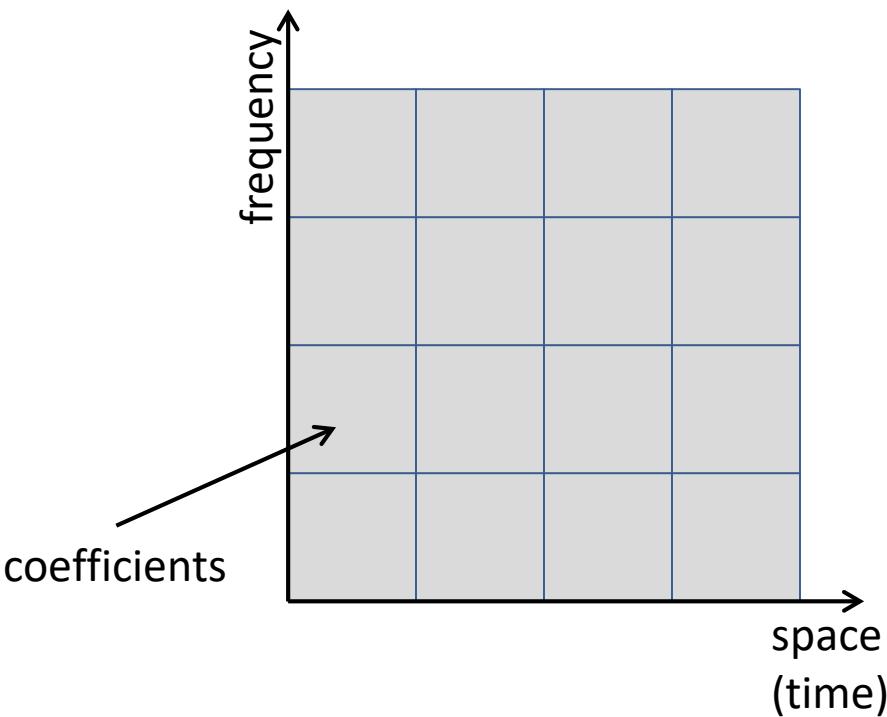

Wavelet Decomposition

Space-Frequency Localization

Wavelet Transform - Example

Original image

2 level DWT

Wavelet Pyramid

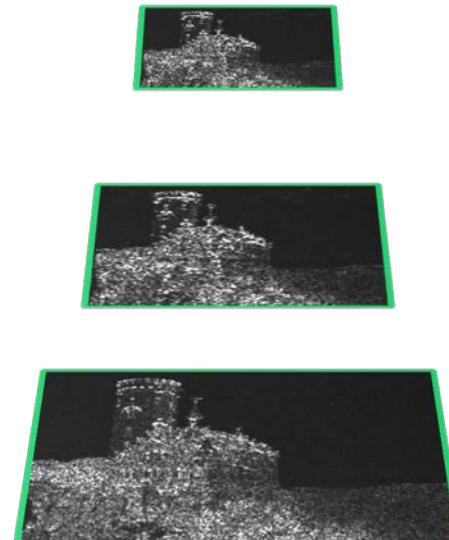

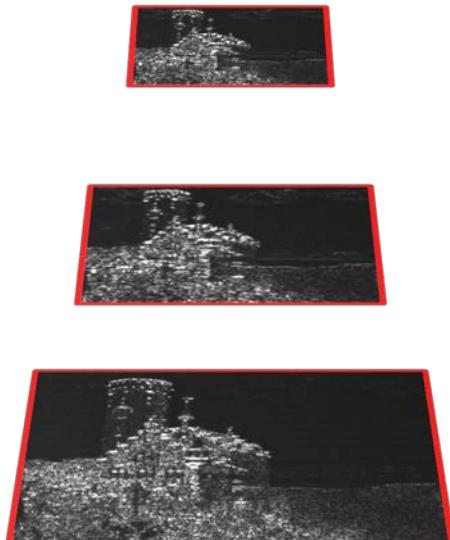

Low-pass residual
(approximation)

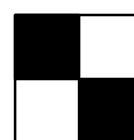

Sub-band
(detail)

scale

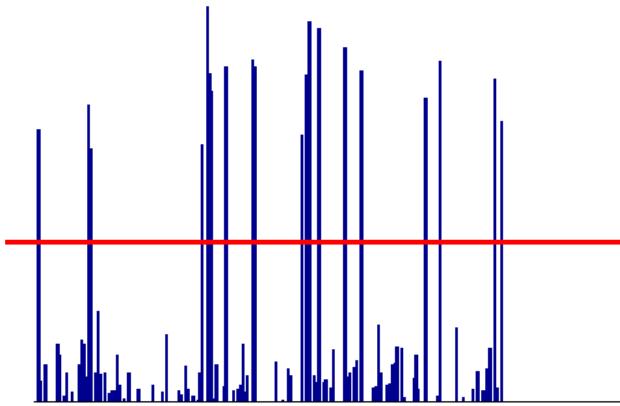

orientation

Wavelet Thresholding (WT)

- Wavelet \Rightarrow Sparser Representation
- Improved separation between signal and noise at different scales and orientations

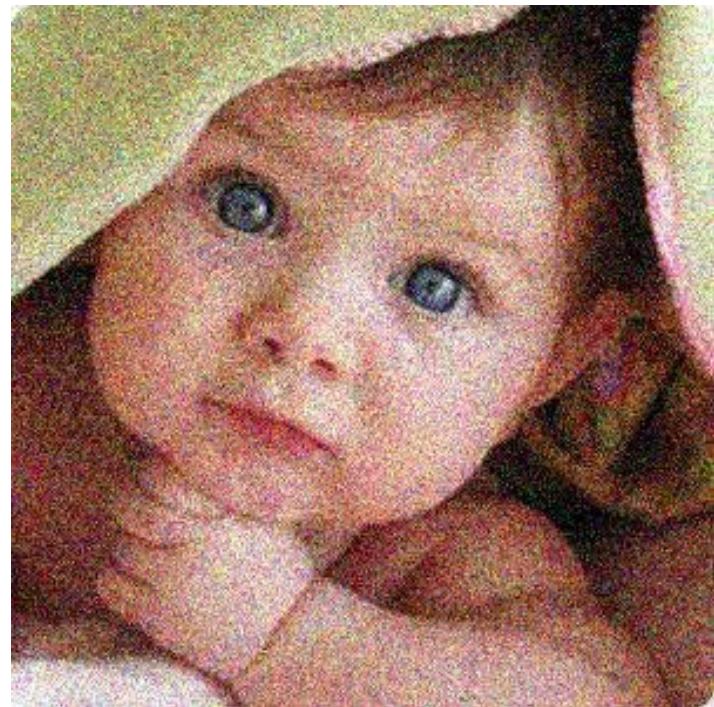

Thresholding (hard/soft) is more meaningful

A Probabilistic Perspective

- Learn or assume statistical model of image and noise - $p(x), p(n)$
- Use Bayesian inference to obtain \hat{x}

Which image do you prefer?

A Probabilistic Perspective

- With some prior knowledge about images
- Denoise = “find an optimal explanation”:
 - **MAP** – Maximum a posterior
 $\hat{x} = \operatorname{argmax}_x p(x|y)$
 - **MMSE** – Minimum Mean Square Error
 $\hat{x} = \operatorname{argmin}_{\hat{x}} E\{(\hat{x}(y) - x)^2\} = E(x|y)$

Taking it up a notch...

State of the art Methods

BLS-GSM-Wavelet Denoising

Bayes Least Squares Gaussian Scale Mixture
Wavelet Denoising
(Portilla *et al.* 2003)

- Transform to Wavelet domain
- Assume GSM model on neighborhoods
- Denoise using BLS estimation

Over Complete Wavelets

- BLS-GSM uses over-complete wavelets

Classical (orthogonal) Wavelets:
 $\# \text{coefficients} = \# \text{pixels}$

Over-complete Wavelets:
 $\# \text{coefficients} > \# \text{pixels}$

Representation is redundant

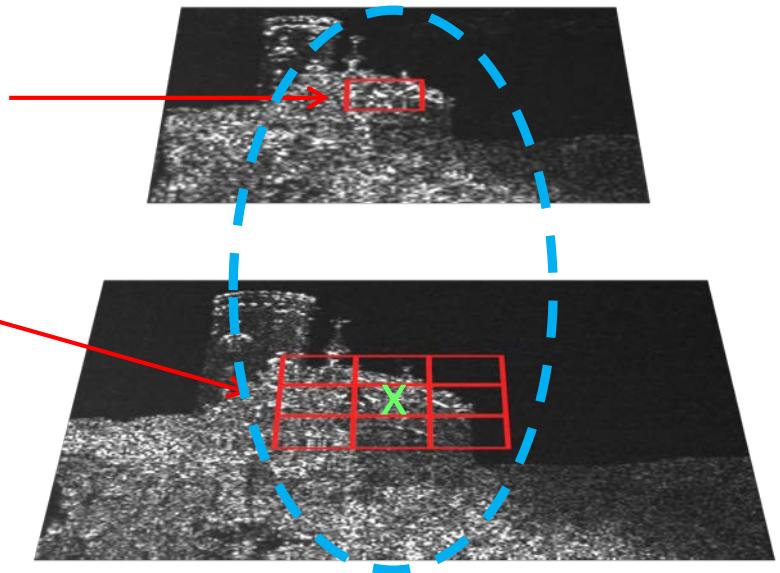

⇒ Combined estimates may improve denoising

Local Neighborhoods

- Spatial-Scale Neighborhood

For example:

- Scale parent of central coef
- 3x3 in space

- Such neighborhoods are highly structured

The GSM model

$$Y = \underbrace{\sqrt{Z}U}_{\text{GSM}} + \underbrace{N}_{\text{Gaussian}}$$

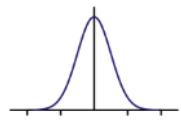

Diagram illustrating the GSM model components:

- $P(z) \sim \frac{1}{z}$: A plot of a power-law-like distribution.
- C_U : A narrow Gaussian distribution centered at zero.
- C_N : A wider Gaussian distribution centered at zero.

Arrows point from each component to its corresponding term in the equation: $\sqrt{Z}U$ and N .

The GSM model

$$z_0 C_U + C_N$$

known

$$Y = \sqrt{z_0} U + N$$

Diagram illustrating the components of the GSM model:

- Y is a Gaussian variable.
- $\sqrt{z_0}$ is a scaling factor.
- U is a Gaussian variable.
- N is a Gaussian noise term.

Everything is Gaussian!

2-Step GSM Denoising

- The Naive approach

For each neighborhood Y :

1. Estimate $Z \Rightarrow X, Y$ are jointly Gaussian
2. Denoise= optimal estimation of $X|Y, Z = z_0$

In MMSE sense:

$$\hat{X}(Y) = E(X|Y, Z = z_0) = z_0 C_U (z_0 C_U + C_N)^{-1} Y$$

This is the Wiener estimate of X

Joint GSM Denoising

- 2-Step is sub-optimal...
- For each neighborhood Y :
Find the MMSE estimator $\rightarrow E(X|Y)$

$$E(X|Y) = \int p(z|Y)E(X|Y, z)dz$$

?

The local Wiener
estimate
(shown last slide)

Posterior distribution of multiplier

- Bayes' rule:

$$p(Z|Y) = \frac{p(Y|Z)p_z(Z)}{\int p(Y|\alpha)p_z(\alpha)d\alpha}$$

Gaussian
(given Z)

Known
(Prior)

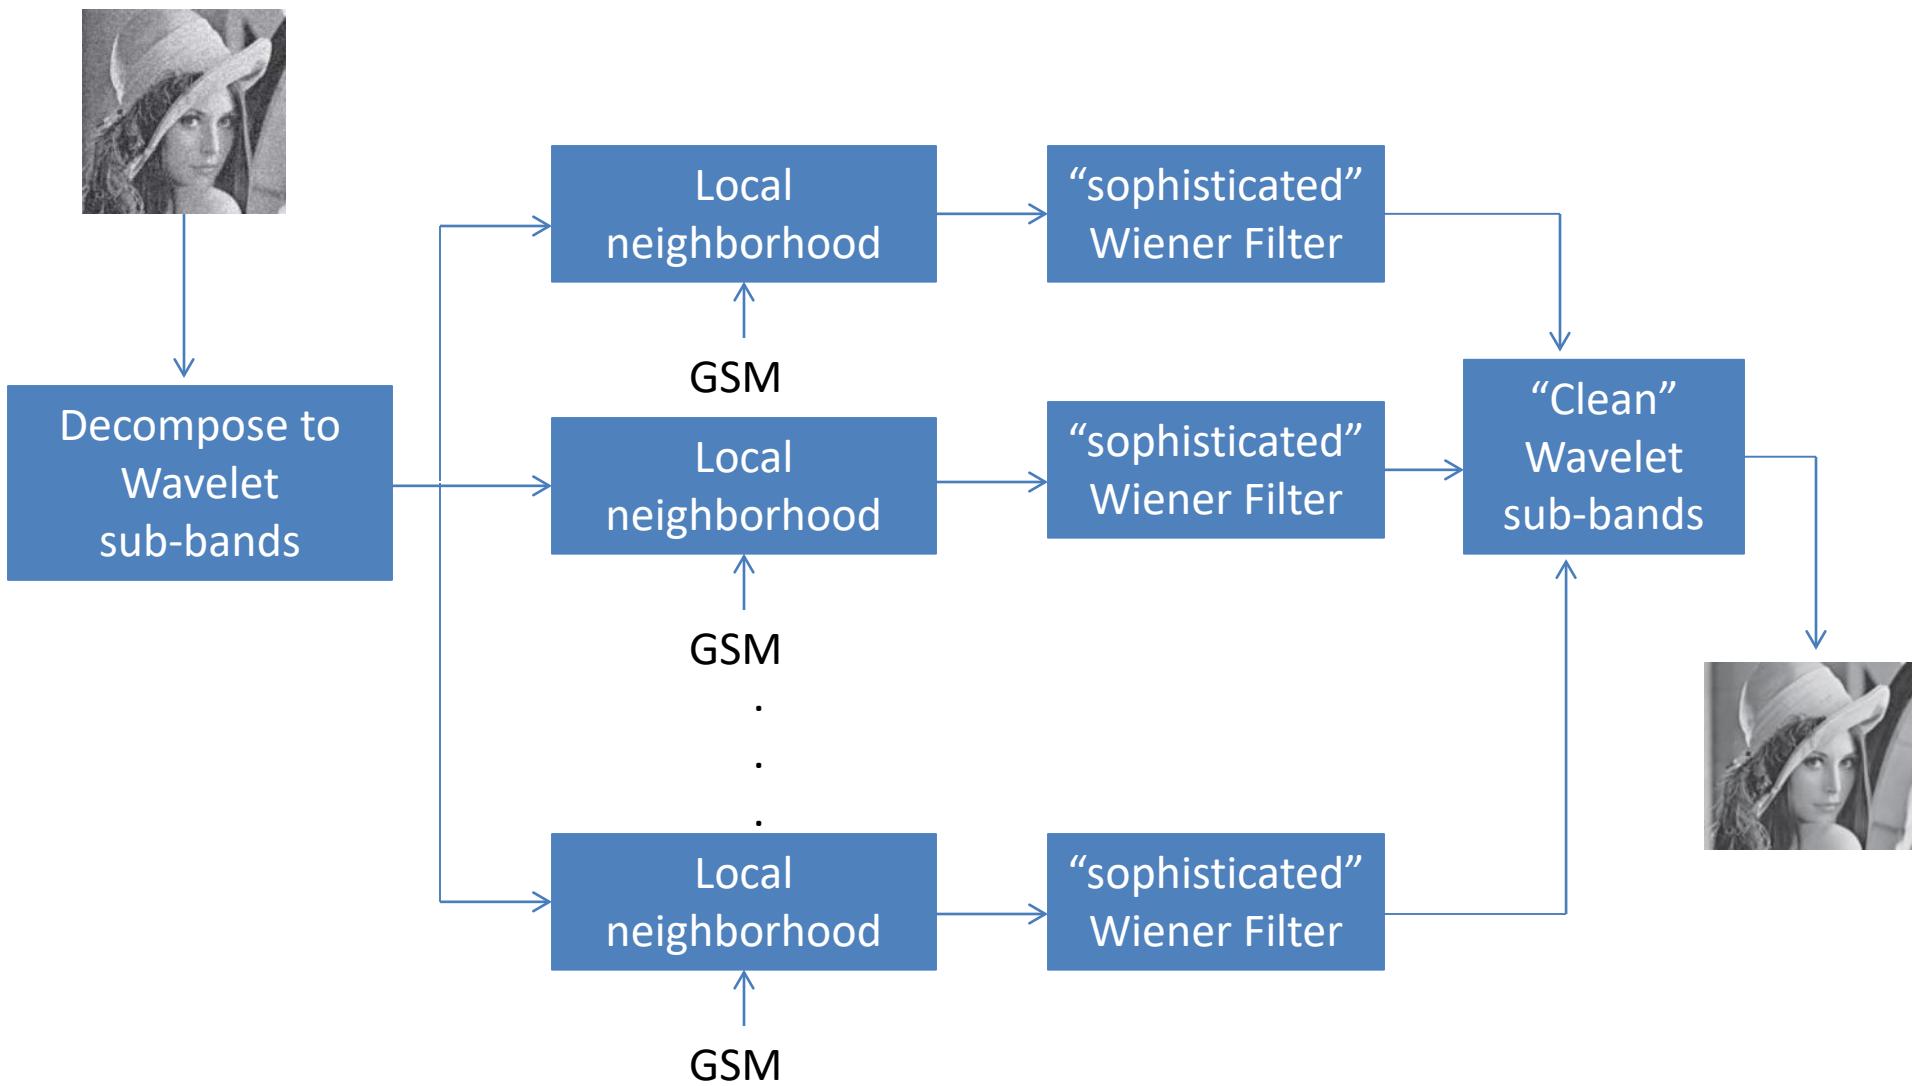

Weighted sum of Wiener estimates

$$\hat{X} = \hat{X} \in \int Y w_z(Y) \int p(\text{Wiener}(X|Y) dz) dz$$

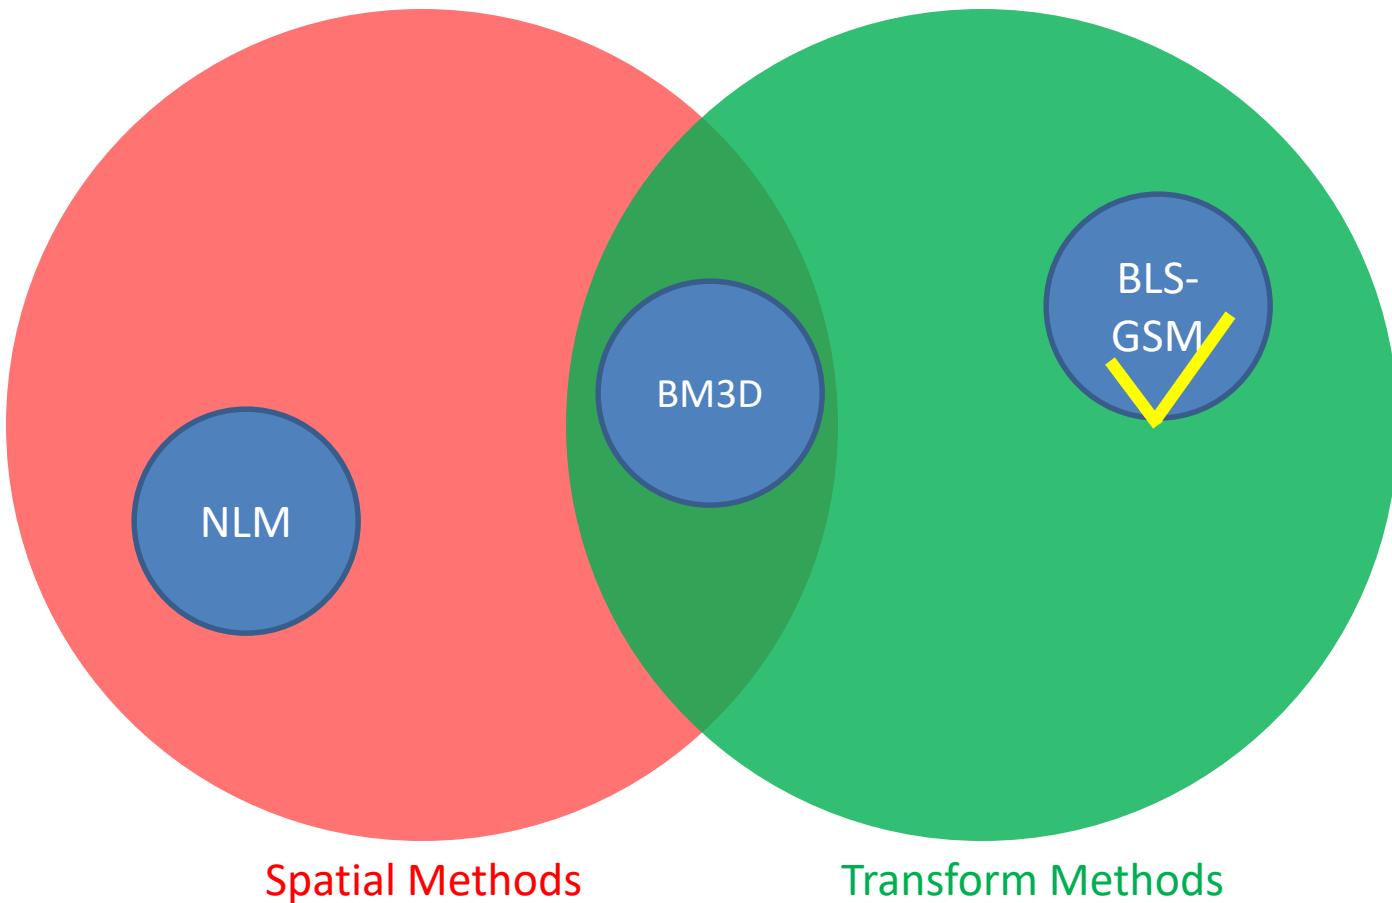

Weighted sum of local Wiener estimates

All z -explanations contribute to the estimate!

BLS-GSM-Wavelet Denoising

State of the art Methods

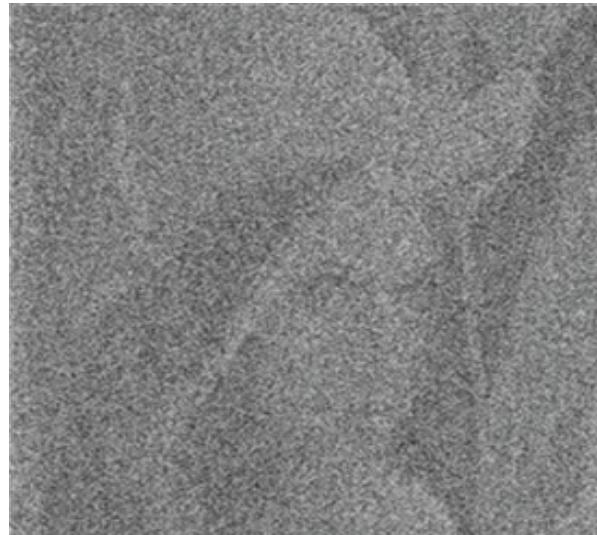

Motivation - Drawback of Locality

- Previous methods perform some local filtering
 - ⇒ mixing of pixels from different statistics
 - ⇒ blur
- Goal:
Reduce the mixing \Leftrightarrow “smarter” localization

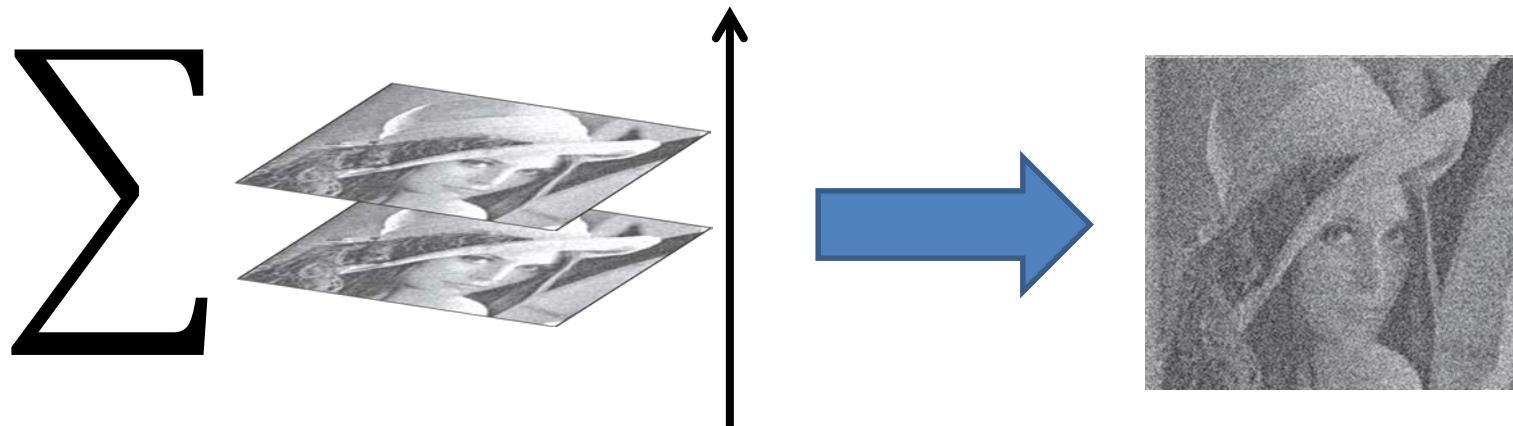

Motivation - Temporal perspective

- Assume a static scene
- Consider multiple images $y(t)$ at different times
- The signal $x(t)$ remains constant
- $n(t)$ varies over time with zero mean

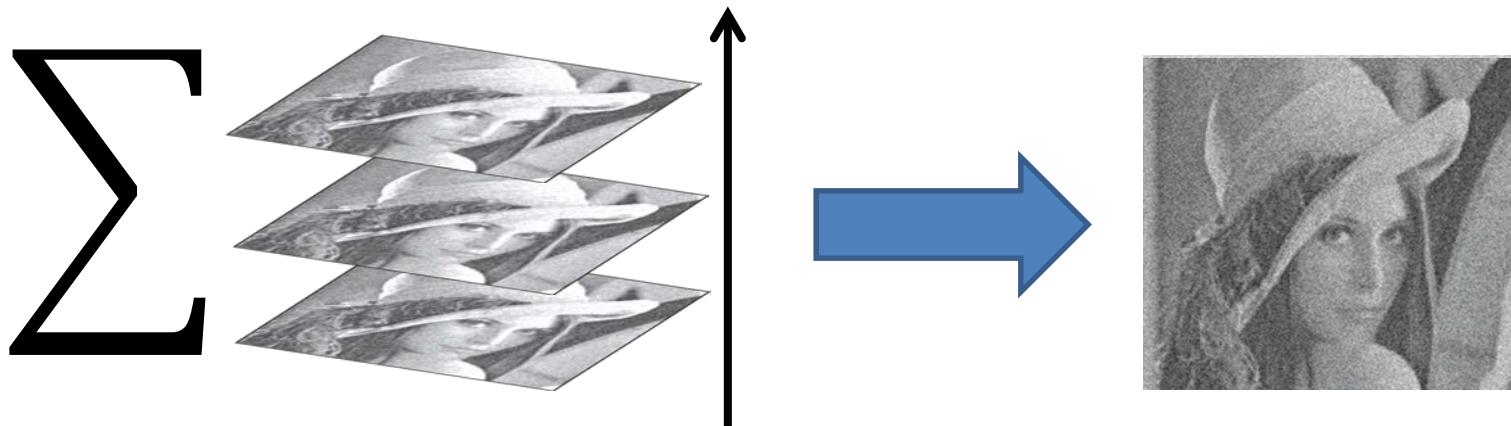

“Temporal Denoising”

Average multiple images over time

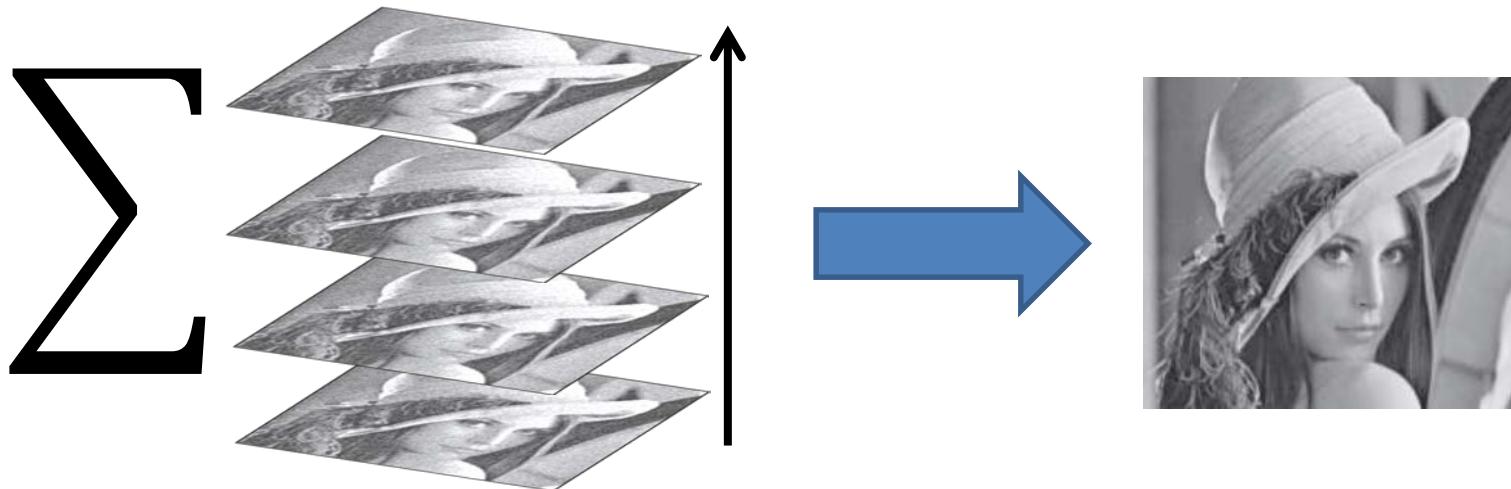

“Temporal Denoising”

Average multiple images over time

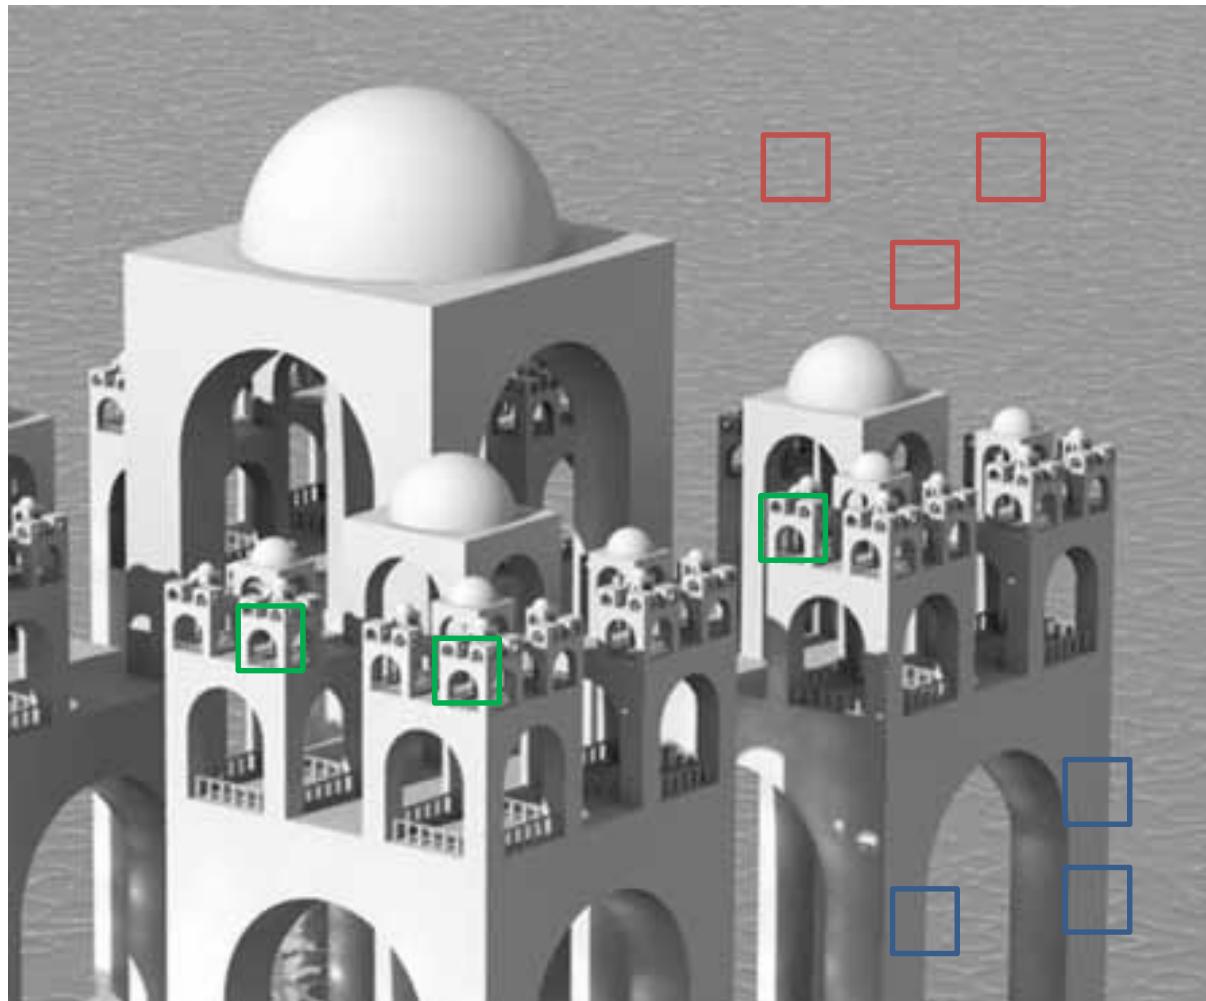

“Temporal Denoising”

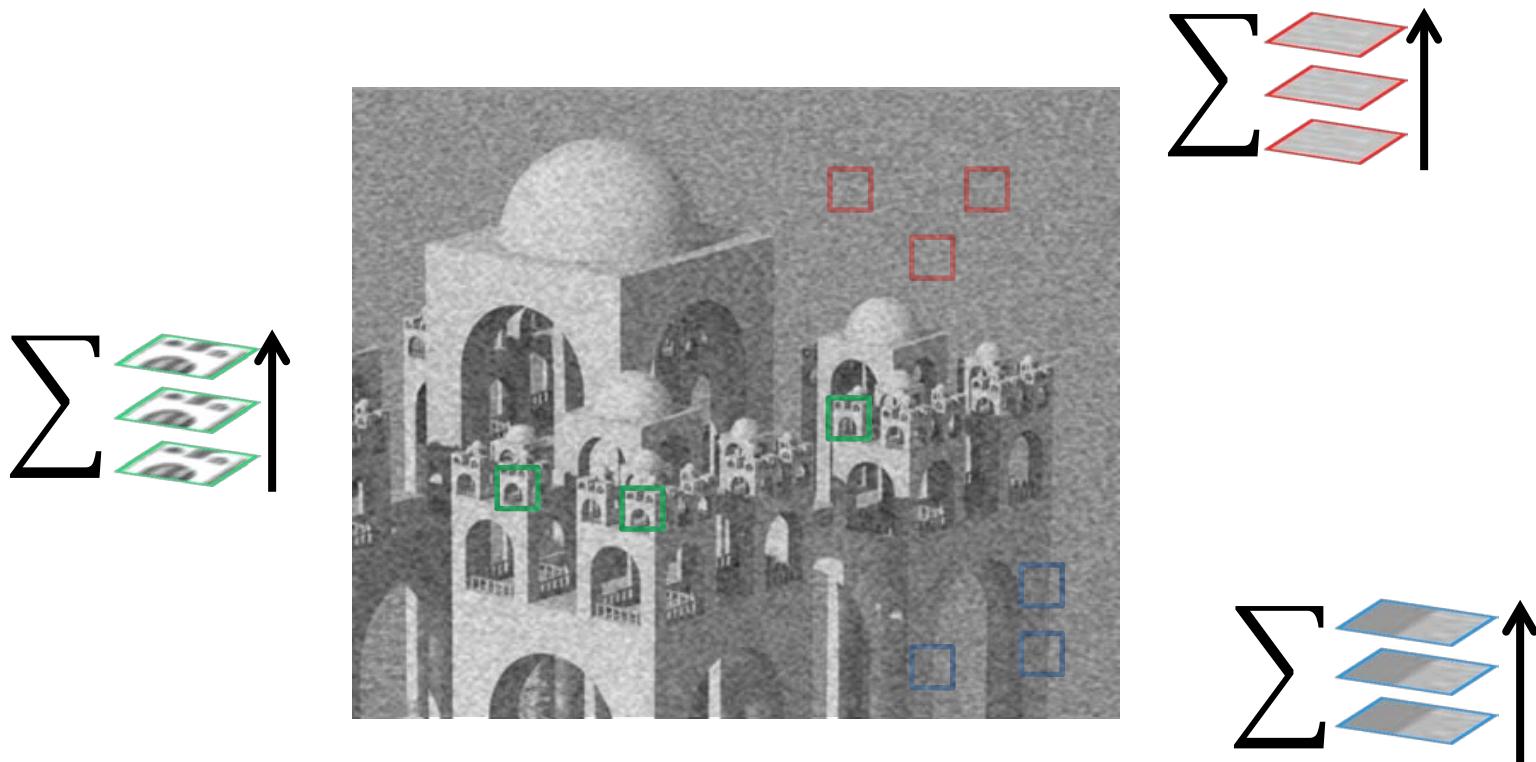

Average multiple images over time

Redundancy in natural images

Single image “time-like” denoising

Unfortunately, patches are not exactly the same
⇒ simple averaging just won't work

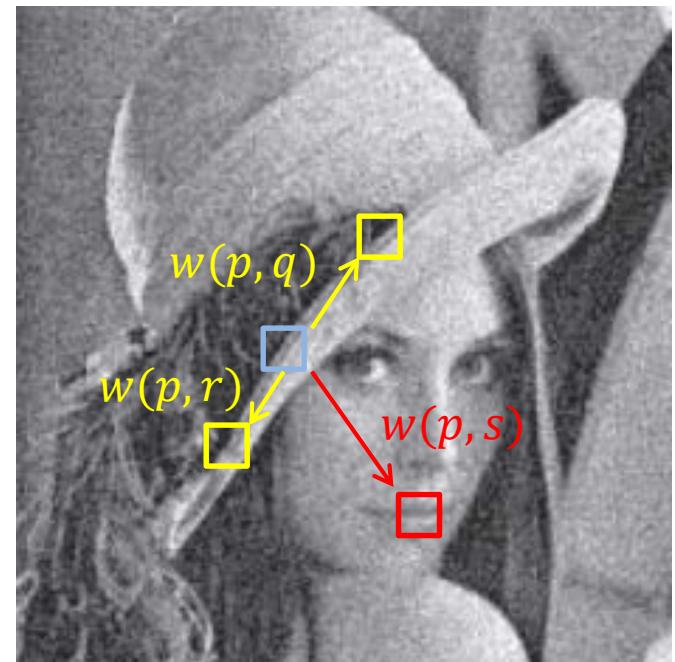

Non Local Means (NLM)

Baudes *et al.* (2005)

Use a weighted average based on similarity

$$\hat{x}(i) = \frac{1}{C_i} \sum_j y(j) e^{-\frac{GSSD(y(N_i)-y(N_j))}{2\sigma^2}}$$

$w(i, j)$

From Bilateral Filter to NLM

$$\hat{x}(i)_{BL} = \frac{1}{C_i} \sum_j y(j) e^{-\frac{|y(i)-y(j)|^2}{2\sigma^2}} e^{-\frac{\|i-j\|^2}{2\rho^2}}$$

intensity weight spatial weight $\rightarrow \infty$

The diagram illustrates the decomposition of the bilateral filter weight function. It shows a red step-like curve representing the product of two exponential functions. The first exponential term, $e^{-\frac{|y(i)-y(j)|^2}{2\sigma^2}}$, is labeled "intensity weight". The second exponential term, $e^{-\frac{\|i-j\|^2}{2\rho^2}}$, is labeled "spatial weight". A blue bracket groups the two terms together, and a blue arrow points downwards from this bracket towards the bottom equation.

$$\hat{x}(i)_{NLM_{1x1}} = \frac{1}{C_i} \sum_j y(j) e^{-\frac{|y(i)-y(j)|^2}{2\sigma^2}}$$

The diagram shows the NLM weight function as a simplified version of the bilateral filter weight function. It consists of a single blue rectangular box containing the term $e^{-\frac{|y(i)-y(j)|^2}{2\sigma^2}}$. This box corresponds to the spatial weight component of the bilateral filter, where the intensity weight component has been removed.

From Bilateral Filter to NLM

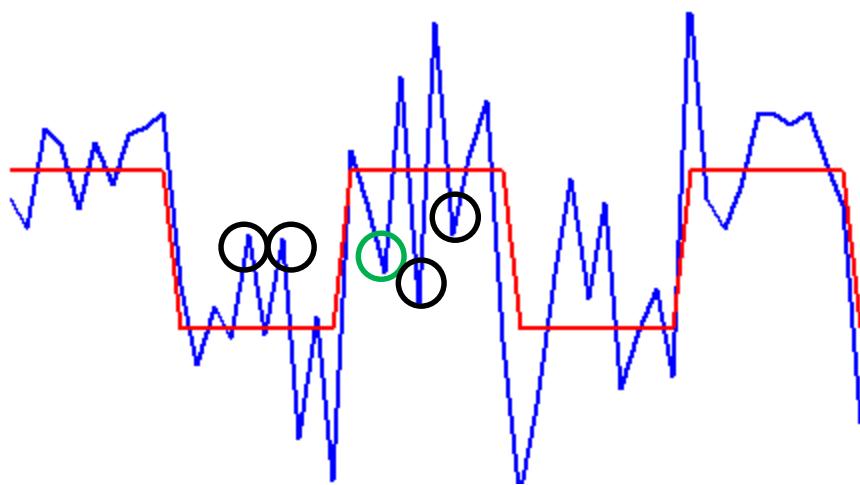

$$\hat{x}(i)_{NLM_{1x1}} = \frac{1}{C_i} \sum_j y(j) e^{-\frac{|y(i)-y(j)|^2}{2\sigma^2}}$$

Patch similarity

$$\hat{x}(i)_{NLM} = \frac{1}{C_i} \sum_j y(j) e^{-\frac{GSSD(y(N_i)-y(N_j))}{2\sigma^2}}$$

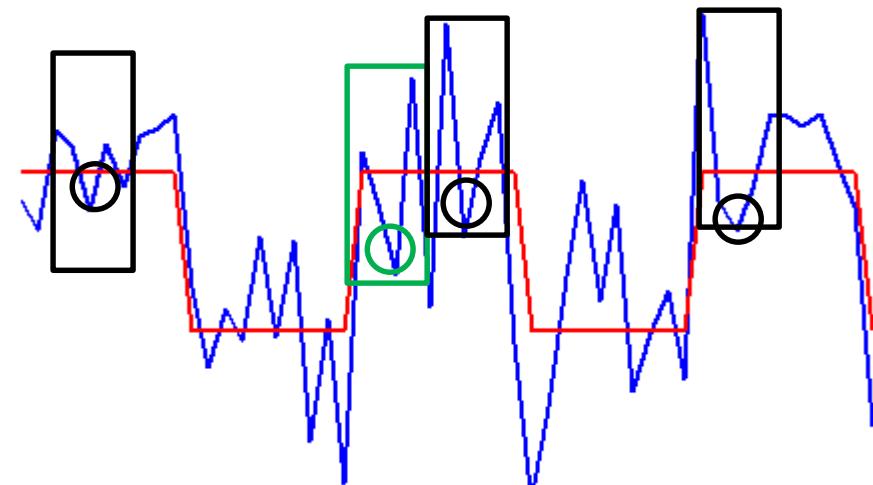

Why NLM is Better?

Bilateral Filtering

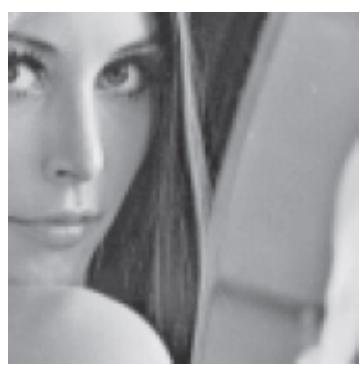

Mixing \Rightarrow bias

Non Local Means

No Mixing \Rightarrow Less bias

Hard WT

Soft WT

What's Next?

- The idea of grouping sounds good
⇒ reduces mixing
- Denoise = “extract the common (the signal)”
- NLM: common = weighted average
- Can a sparser representation do better?

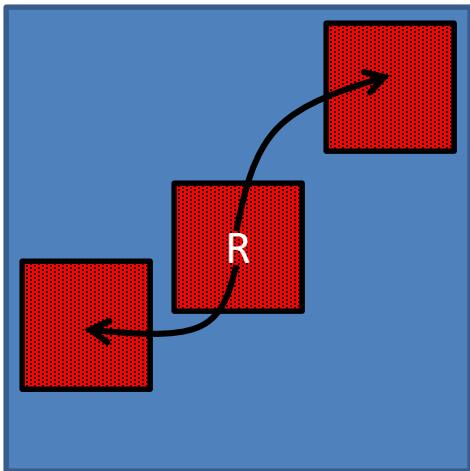

BM3D

Block Matching 3D collaborative filtering
(Dabov *et al.* 2007)

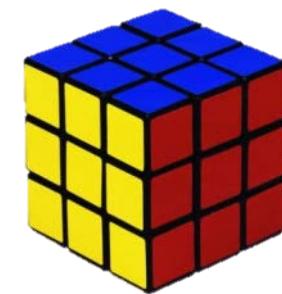

- Group patches with similar local structure (**BM**)
- Jointly denoise each group (**3D**)
- Smart Fusion of multiple estimates

A Single BM3D Estimate

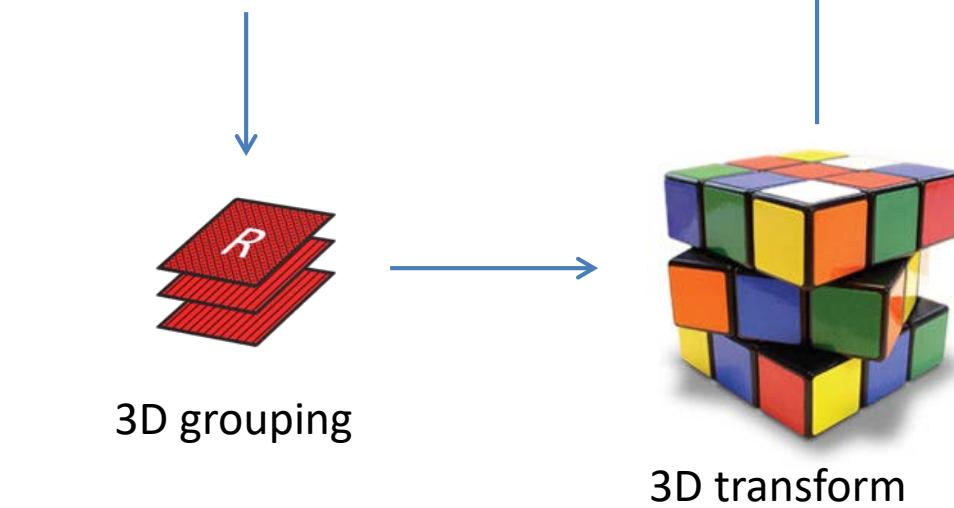

Block matching

Inverse 3D transform

Filter / thresholding

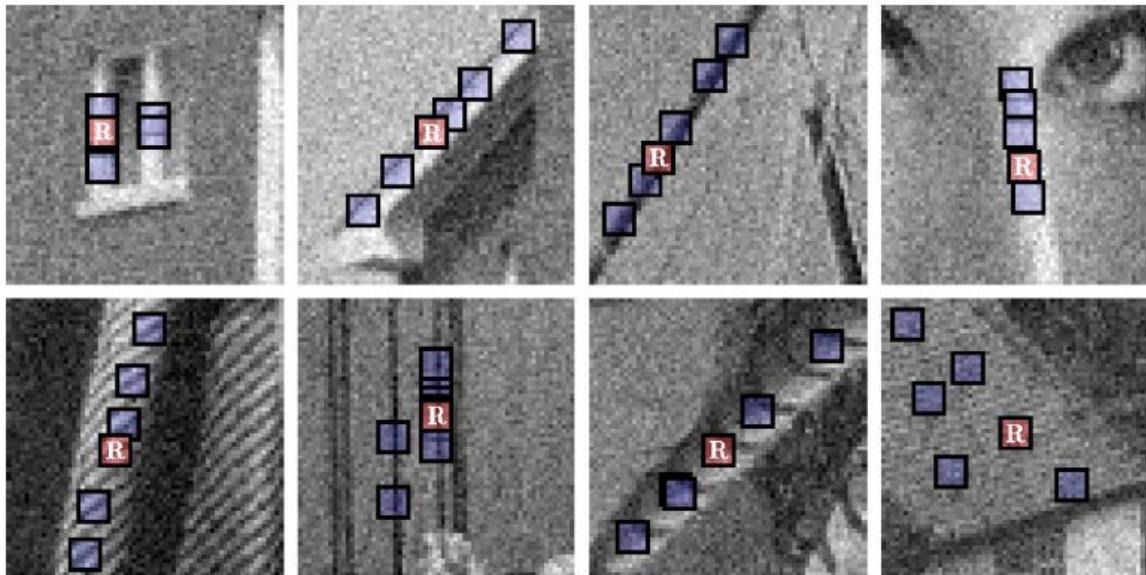

3D grouping

3D transform

Denoised 3D group

Grouping by Block Matching

- For every noisy reference block:
 - Calculate SSD between noisy blocks
 - If $\text{SSD} < \text{thr} \Rightarrow$ add to group

3D Transform

Reminder:

2D transform

Sparicity

α

naive
approach:

2D transform

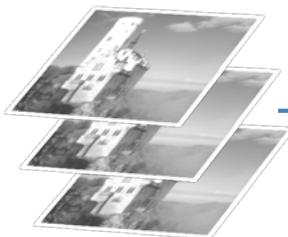

2D transform

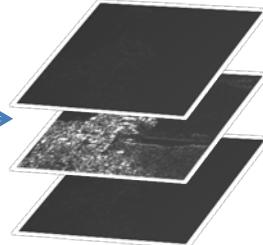

$k\alpha$

BM3D
approach:

3D transform

α

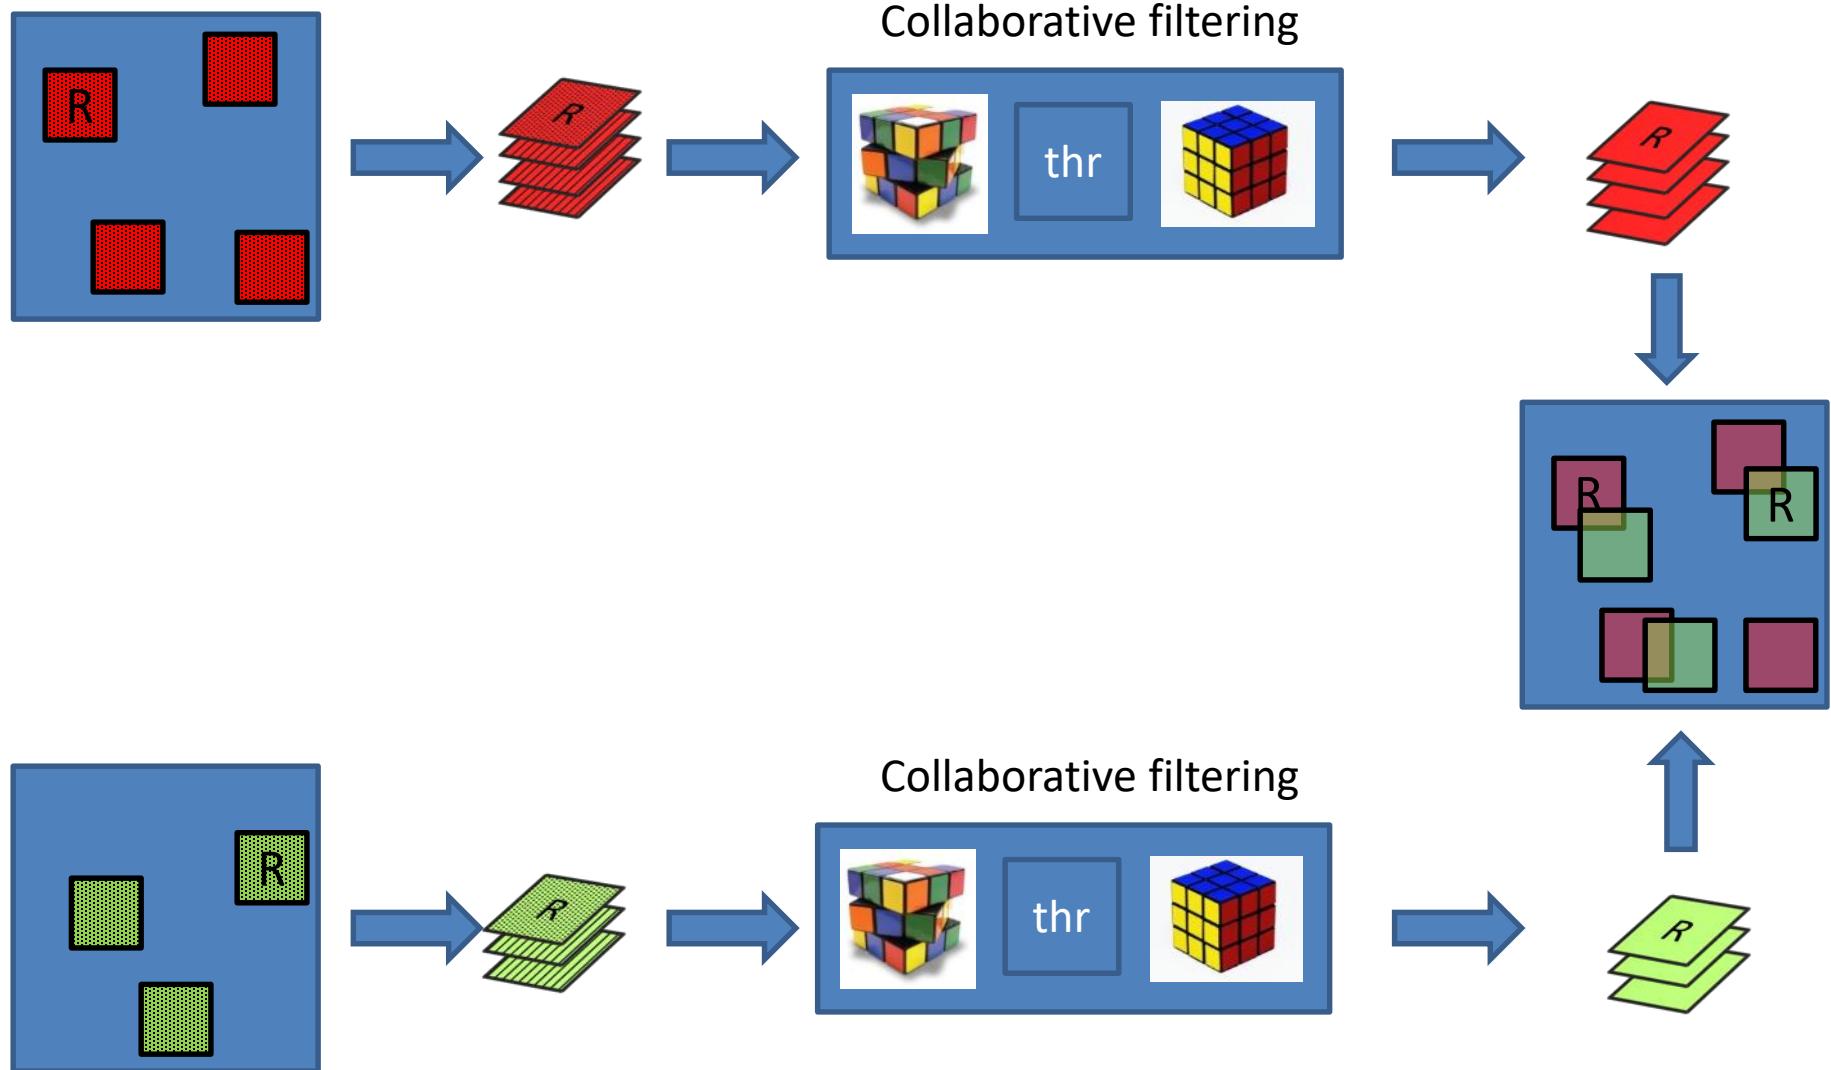

Collaborative Filtering

- Use hard thresholding or Wiener filter
- Each patch in the group gets a denoised estimate

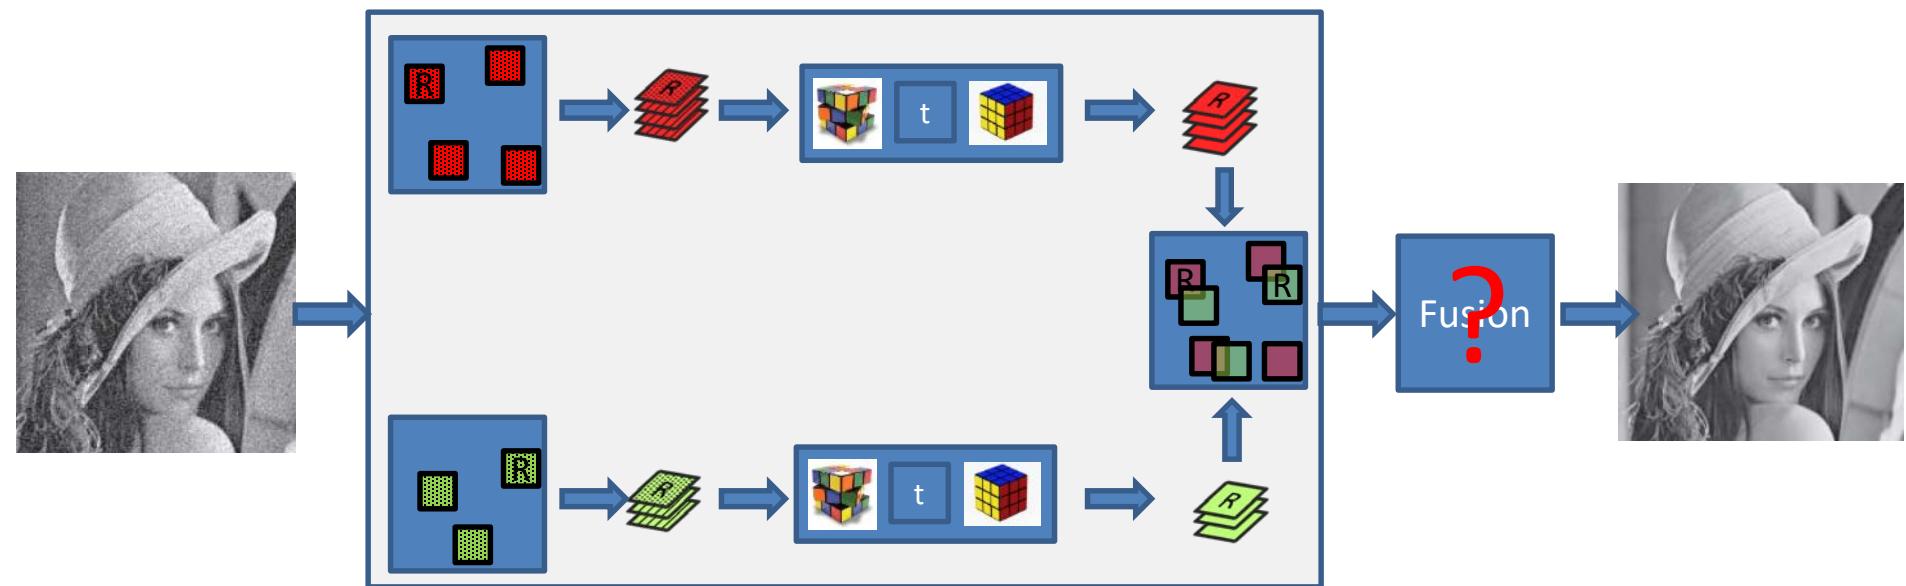

- Unlike NLM – where only central pixel in reference patch got an estimate

Multiple BM3D Estimates

Basic BM3D Denoiser

Fusion

- Each pixel gets multiple estimates from different groups
- Naive approach
Average all estimates of each pixel
.... not all estimates are as good
- Suggestion
Give higher weight to more reliable estimates

BM3D - Fusion

- Give each estimate a weight according to denoising quality of its group
- Quality = Sparsity induced by the denoising

Hard thresholding

$$w \propto \frac{1}{\#Non\ Zero\ Coefficients}$$

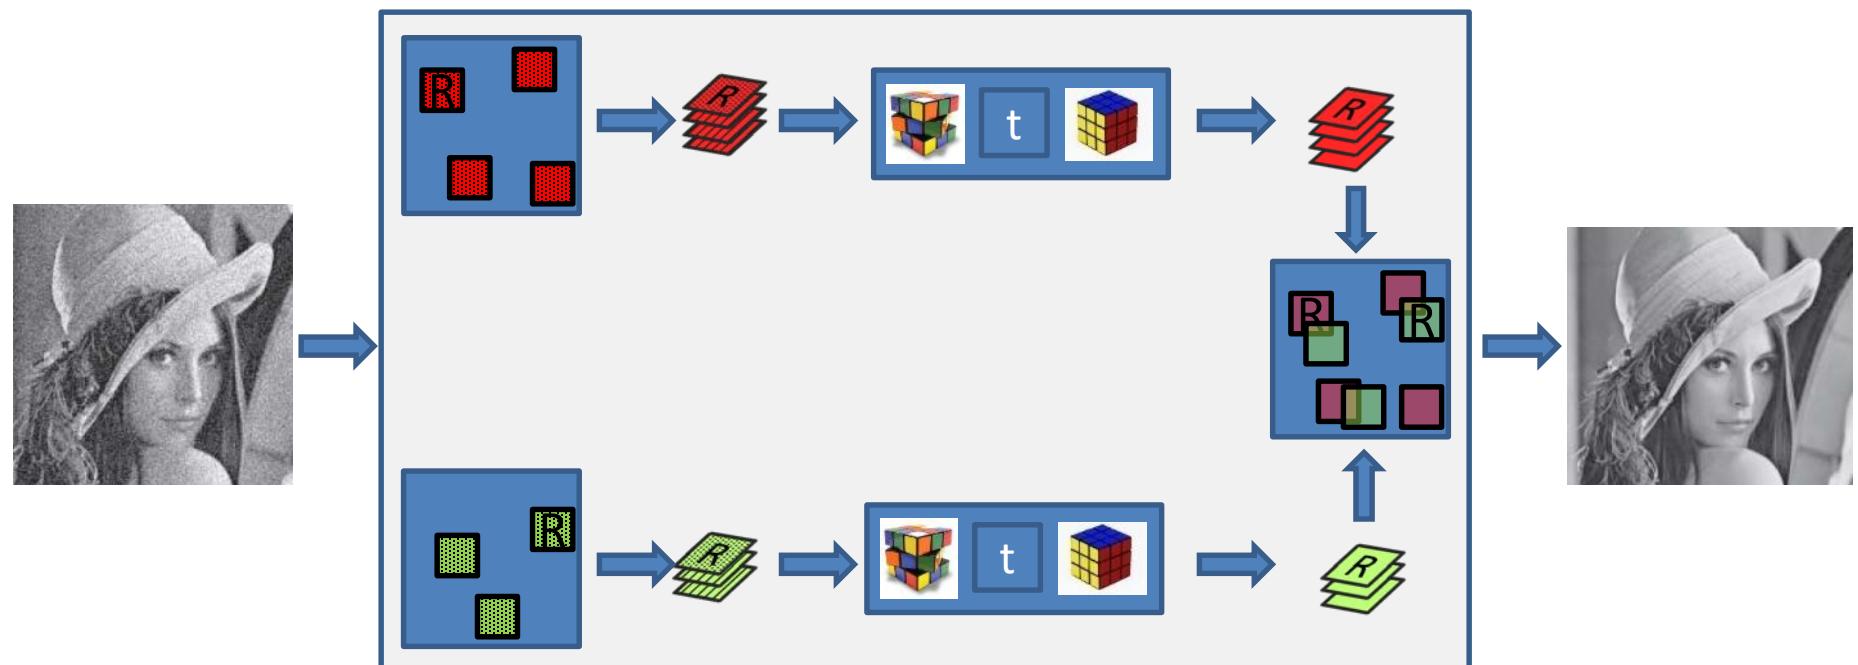

Weiner filtering

$$w \propto \frac{1}{\|Filter\|^2}$$

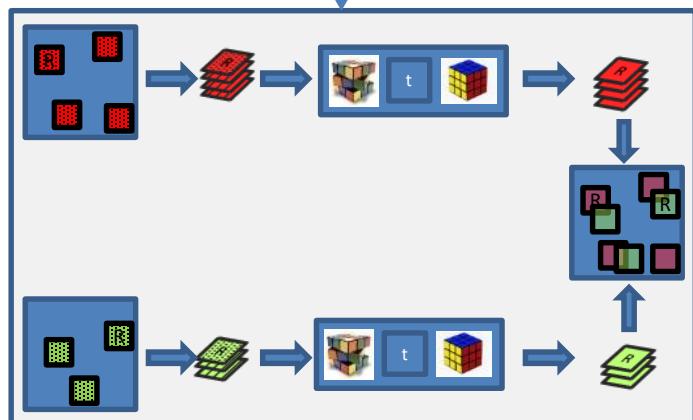

BM3D in Practice

- Noise may result in poor matching
⇒ Degrades de-noising performance
- Improvements:
 1. Match using a smoothed version of the image
 2. Perform BM3D in 2 phases:
 - a. Basic BM3D estimate ⇒ improved 3D groups
 - b. Final BM3D

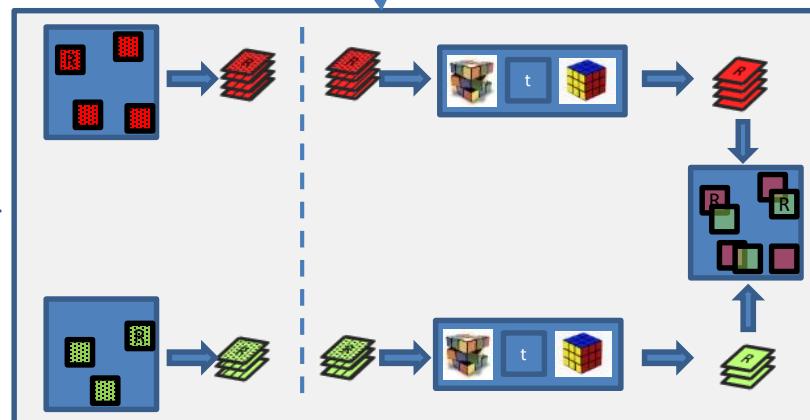

Basic BM3D Denoiser

Two phase BM3D Denoising

(a)
Basic denoising:
Hard thresholding

(b)
Final denoising:
Wiener filtering

Results and Comparison

- Comparison:
 - Different levels of noise
 - Different sets of images
- Evaluation methods:
 - MSE/PSNR
 - Visual comparison to noisy and/or original images

BM3D □

Comments

- Average improvement from naive Gaussian filtering to NLM – 4-5 dB
- Average improvement of 1 dB over 4 years (from BLS-GSM(2003) to BM3D(2007))
- Saturation in PSNR over the last 4 years (BM3D still considered state of the art)

Any questions?
